for their performance a profound narcosis in order to prevent reflex movement, retching, or other incidents which might embarrass the surgeon or prejudicially affect the success of the operation. The laryngeal, peritoneal, rectal, vesical, and ocular reflexes are amongst the latest to disappear, so that in operations upon these parts full narcosis is usually necessary. The local application of cocaine is a most useful adjunct to chloroform anæsthesia in intra-laryngeal operations, for it enables the anæsthetist to work with a somewhat lighter chloroform anæsthesia than would otherwise be necessary. One of the greatest problems of the modern anæsthetist is the maintenance of deep anæsthesia during certain intra-abdominal manipulations. Whilst there can be no doubt that such an anæsthesia is convenient, and in some cases almost essential to the surgeon, it certainly cannot always be obtained in horizontally placed patients under chloroform without directly subjecting them to the risk of surgical shock of a circulatory type. When this profound anæsthesia is desired it is often wise, therefore, to employ ether. In some cases the administration of morphine before or during chloroform anæsthesia is very useful. When muscular relaxation is essential, as in the reduction of dislocations, abdominal examinations, &c., deep anæsthesia must also be obtained, but great care is necessary not to exceed the limits of safety. On the other hand, most operations within and about the upper air-passages, and particularly those in which hæmorrhage is profuse, require only a moderate anæsthesia; and the same may be said of most operations upon the lungs and pleuræ. It is a mistake, for example, to keep up a very deep chloroform anæsthesia for operations upon the thyroid gland, for those involving the deep structures of the neck, and for operations upon the brain and spinal cord, and the same may be said of those intra-abdominal cases which admit of being conducted during moderate anæsthesia. Another factor in the adjustment of the strength of vapour is the particular stage of the operation in hand. We have already seen that deep anæsthesia should, as a rule, be secured before the operation commences, and that from this point onwards a slight trace of corneal reflex should, if possible, be preserved. There is a point in many administrations which may be called the "critical juncture," and at this point great care is always necessary lest the anæsthesia be too profound. It occurs in abdominal cases just when the abdomen is being opened or just afterwards; in cases of nephrectomy when the pedicle is being pulled upon; in prostatectomy when the urethra is being torn through; and in hysterectomy when traction is at its height. In order to prevent reflex movement at the moment of the skin incision and abdominal rigidity subsequently, the anæsthetist is often tempted in abdominal surgery to push the anæsthetic unduly at the commencement, and if chloroform be the agent in use two risks are thereby incurred—that of overdosage and that of circulatory shock when the abdominal manipulation commences. Contrary to time-honoured doctrines, I would submit to you that at all these junctures the anæsthesia, though deep, should not be too profound. In operations within and about the throat and nose, attended by free hæmorrhage, there is also a critical juncture. It arises at the beginning of the operation—i.e., before the larynx has taken on, and has become practised in, its new function—that of preventing (by swallowing and coughing) the entry of blood into its cavity. In these cases great care must be exercised at the point indicated. There are many operations in surgery in which the manipulations of the surgeon successively involve organs or regions differing widely in their sensibility, and it is often necessary, therefore, to vary the strength of anæsthetic vapour *pari passu* with these manipulations. Sometimes, of course, it is quite impossible to reduce the strength of anæsthetic at the desired moment owing to the surgeon requiring complete muscular relaxation, and it is under such conditions that a change from chloroform to ether is advisable. Profuse or protracted hæmorrhage during any operation should generally be taken to indicate a lessening of the depth of anæsthesia; and the same may be said of cases in which circulatory shock has occurred, and of those in which unavoidable intercurrent asphyxia is present. Considerable practice is necessary in the adjustment of these different strengths of anæsthetic vapour, particularly if no regulating apparatus be used. At the same time such adjustments have their great advantages not only in the direction of providing the surgeon with the anæsthesia required, but also in the direction of ensuring satisfactory recovery.

The Croonian Lectures

ON

PLAGUE.

Delivered before the Royal College of Physicians of London on June 18th, 20th, 25th, and 27th, 1907,

BY W. J. R. SIMPSON, M.D. ABERD., F.R.C.P. LOND.,

PROFESSOR OF HYGIENE AT KING'S COLLEGE, LONDON; GOVERNMENT COMMISSIONER TO INQUIRE INTO CAUSES AND CONTINUANCE OF PLAGUE IN HONG-KONG, 1902, ETC.

LECTURE III.[1]

Delivered on June 25th.

IMMUNISATION AGAINST DISEASE.

MR. PRESIDENT AND FELLOWS,—The next question from a preventive aspect is whether there is a prophylactic against plague similar to that of vaccination against small-pox, and if so what is its value. The question naturally leads to a consideration of Haffkine's prophylactic against plague and of methods of artificial immunisation. Jenner's great discovery lay in the fact that he ascertained that the passage of the small-pox virus through the cow fixed its properties in such a manner that the immunising effects of the small-pox virus were retained while its power of producing the disease was destroyed. The defects of inoculation with the small-pox virus consisted in the danger to the inoculated which sometimes attended the operation and in the risk of infection which sometimes spread from the inoculated to other persons. Notwithstanding these disadvantages inoculation was practised as the lesser evil because in the majority of cases its effects were comparatively mild and it conferred a very high protection. Inoculation against disease is thus a very old method of protection. In some of the ancient shastras written contemporaneously with the works of Menoo inoculation is mentioned as being practised as a preventive or modifier of small-pox. Even inoculation against plague has been practised among the Turks.

The Brahmins who performed the inoculations against small-pox in India instituted certain procedures to avoid the defects as much as possible. They made it a point to inoculate if possible all the children in the village at the same time so as to prevent natural infection; they selected the virus from a discrete case and they usually kept it several days before inoculating it into individuals, for they found by experience that it produced a milder disease when thus kept than when directly transmitted from person to person. In later times such precautions were often relaxed with results not nearly so satisfactory. In China the inoculations against small-pox were often practised by ignorant men and instead of the small-pox virus being inoculated through the skin, which generally gives a mild attack, it was not infrequently placed in the nostrils and a very severe attack of the disease usually followed. When in China I came across an instance of this kind where some 17 persons had been inoculated in this manner and where the results were serious.

The older methods of inoculation, whether for small-pox or plague, depended on the employment of crude material containing the living germs of the disease and over these there was little or no control. Sometimes the material was efficacious and harmless, at other times it was dangerous. There was also risk of the method, while protecting the individual inoculated, spreading the disease to healthy persons. The discoveries of Jenner, Pasteur, and Haffkine have introduced new methods by which the material employed is fixed in strength, protective and harmless to the individual, does not spread the disease, and is fully under control.

HAFFKINE'S CHOLERA VACCINATION.

There is a difference between the cholera and plague inoculations introduced by Haffkine. In cholera a living vaccine is employed; in plague a devitalised or chemical vaccine is used. The cholera vaccine needs to be fixed in its strength in order that the microbe shall behave constantly in the same manner when injected alive into man. It was the non-recognition of this fundamental principle which led to

---

[1] Lectures I. and II. were published in THE LANCET of June 29th (p. 1757) and July 13th (p. 73), 1907, respectively.

SIR WILLIAM H. BROADBENT, BART., K.C.V.O., M.D., F.R.S., &C.

(From a photograph by Messrs. Elliott and Fry.)

by the inoculation at any time more susceptible to these diseases than the uninoculated.

THE RESULTS OF THE USE OF THE PROPHYLACTIC.

The harmlessness of the prophylactic was first established by the inoculation of several hundred volunteers, European and Indian. Then its protective effect was ascertained for the first time at the height of an outbreak of plague at the Byculla jail and certain facts were observed by Haffkine which enabled him to arrive at some very important conclusions. These were: (1) that one injection of three cubic centimetres of the prophylactic was sufficient to protect during an existing epidemic; (2) that inoculation was powerless to arrest the disease in those in whom the symptoms have already appeared or develop in a few hours after inoculation; (3) that the inoculation mitigated or aborted the disease in those who were in the incubation stage and had been infected three or four days previously; and (4) that the prophylactic, unlike the vaccines for cholera, rabies, anthrax, or small-pox, exercised its protective effect in less than 24 hours, acting in this respect with a rapidity which was only known in antitoxic sera.

CLASS I.—TABLE A.

OBSERVATIONS ON THE WORKING OF HAFFKINE'S SYSTEM ON A SMALL SCALE, SPECIAL OBSERVATIONS BEING CARRIED OUT ON RESTRICTED COMMUNITIES.

Name of locality.	Non-inoculated.						Inoculated.

* Four deaths occurred among the prisoners before inoculation. The entire population was inoculated. One case occurred two days after inoculation, which recovered.

† Population 334. Plague continued for 37 days and 23 cases and 17 deaths occurred. Gradually the whole population was inoculated and none of those inoculated were attacked.

‡ Population 1661. Plague continued for 13 days and three cases and three deaths occurred in those who had not been inoculated. 1658 were inoculated by the thirteenth day; of these one was attacked but recovered. There were no further cases.

§ All the prisoners were inoculated excepting two; these two were attacked, one of whom recovered. When inoculation completed no cases, although rats were dying from plague.

¶ Admissions.

These observations were made in places where non-inoculated people had between 1·2 and 100 per cent. of cases and between 0 6 and 66·7 per cent. of deaths, with a proportion of deaths to cases varying between 50 and 100 per cent. The inoculated people of the same places had between 0 and 11·3 per cent. of cases and between 0 and 4 2 per cent. of deaths, with a proportion of deaths to cases varying between 0 and 57 1 per cent. The number of cases among the inoculated was reduced by between 68 3 and 100 per cent., and the number of deaths by between 79·5 and 100 per cent., as compared to the incidence of attacks and deaths among the non-inoculated people of the same place.

Of these deductions that relating to the effect of the vaccine on individuals in the incubation stage and its power of arresting the development of infection or mitigating the disease appears to be the most incredible, particularly in view of the shortness of the incubation period in plague. Calmette and his co-workers as well as other bacteriologists asserted that an individual inoculated not only in the incubation period but also a short time before infection would succumb to the disease and recommended that no "contacts" or persons exposed to infection should be inoculated. The Indian Plague Commission of 1889, though not endorsing this view, was of opinion that inoculation was not likely to effect any protection for the first five days and was against Haffkine's conclusion as to the benefit of the inoculation in the incubation period. Subsequent study of the subject, however, induced Sir Almroth E. Wright to adopt Haffkine's views, and it is in conformity with the results obtained by Haffkine's inoculation in the incubation stage of plague that he based his opsonic method of treating with vaccines patients suffering from furunculosis, sycosis, acne, and other bacterial infections. The fact of the prophylactic immunising so rapidly and being beneficial in the incubation stage not only excludes the danger that was feared but allows of the application of the prophylactic in infected houses and localities, and generally during the prevalence of an epidemic.

Later observations have fully confirmed Haffkine's conclusions which stand to-day without modification. It is not from observations on animals but from observations on man that the question as to the action of Haffkine's prophylactic has to be worked out and has to be judged. This test has now been applied in many places and under various conditions and always with the same successful result. The observations are divisible into two classes—viz., those that have been made on a small scale in restricted communities living under special administrative and medical control, and those made on a large scale. Owing to the circumstances in which the first class, conducted on a small scale, were carried value in helping the student to appreciate the natural history of a lesion the correct interpretation of which often causes considerable trouble. The sections on prognosis were founded on matter which in the original lectures was very controversial, and it cannot be doubted that Broadbent's sound teaching on the point considerably helped the profession to the formation of the views which are now generally held. Other official lectures which he delivered were the Lettsomian, in which he considered Syphilitic Affections of the Nervous System, and in 1894 the Cavendish lecture on Some Points in the Treatment of Typhoid Fever. We had the pleasure of publishing all these dissertations in THE LANCET and know fully that their practical value was appreciated by our readers. He held office in many prominent medical societies, being successively president of the Harveian Society of London, the Medical Society of London, the Clinical Society, and the Neurological Society. In 1888-89, and again in 1895-96, he was a Censor of the Royal College of Physicians of London, and on at least two occasions he was within an ace of being elected to the presidency of that distinguished corporation.

In 1892 Broadbent was appointed physician-in-ordinary to H.R.H. the Prince of Wales, now our King, and the following year Queen Victoria conferred a baronetcy on him on the occasion of the marriage of the present Prince of Wales, then Duke of York, whom he had attended in an attack of typhoid fever two years previously. In 1898 he was appointed physician-extraordinary to the late Queen and he was physician-in-ordinary to His Majesty the King and to H.R.H. the Prince of Wales, which offices he held at the time of his death. He was, moreover, the recipient of many academical distinctions, being made an honorary LL.D. of Edinburgh in 1898 and of St. Andrews in the following year. In 1904 the University of Leeds made him an honorary Doctor of Science, and he received his last degree *honoris causâ* as late as the September of 1906, when the University of Toronto in special convocation conferred on him its LL.D. on the occasion of the meeting of the British Medical Association in that city. In 1897 Broadbent received the blue ribbon of the scientific world, when his memoirs bearing on the physiology and pathology of the nervous system and heart and also on the scientific principles of therapeutics gained him the Fellowship of the Royal Society. In 1896 he retired from active service on the staff of St. Mary's Hospital and in the following year he was presented by his former colleagues and students with a handsome service of silver plate in recognition of his merits as a clinician and teacher.

During the best years of his life he took a very active interest in all schemes of a corporate nature to promote either the welfare of his profession or the health of the nation. That by which he best deserves remembrance as showing such a fine side of his character is the British Medical Benevolent Fund, of which he was treasurer and president for many years, and on behalf of which he made frequent appeals in our columns. The problem of tuberculosis greatly occupied his attention. He was chairman of the council of the National Association for the Prevention of Tuberculosis and took a prominent part in connexion with the King's Sanatorium; he was very anxious to see some scheme carried through for the national provision of sanatoriums for workers. Another object which was very close to his heart was the establishment of a central body for the control of the London hospitals that would avert a clashing of interests between the various hospital funds. At one time he devoted a good deal of attention to the question of the duration of quarantine and infectivity in contagious disease and in 1889 he wrote on this important matter. He was a vice-president of the Cancer Research Society, and we may repeat that there was scarcely any great movement organised in behalf of national public health which did not gain his active support. We may quote other instances in the movement in favour of teaching hygiene and temperance on which he both wrote and spoke in 1905 and his support of the colonies for epileptics. He was a governor of Epsom College and he took a keen interest in his old college at Manchester, where he delivered an introductory address in 1892. We have mentioned that he maintained a lively interest in foreign medicine; he was an honorary member of many distinguished societies, such as the Verein für Innere Medicin, Berlin, the Imperial Society of Constantinople, and the Société Médicale de Genève. It was to the medical profession in France, however, that his name was best known. On the occasion of the banquet given to the French physicians and surgeons by their English colleagues when they visited London in the autumn of 1904 Sir William Broadbent made a most admirable and urbane chairman, and at the return visit to Paris during the next year he replied for the English guests at the banquet at the Grand Hotel, under the chairmanship of Professor Bouchard. This occasion must have been to Sir William Broadbent one of the most memorable of his life, for after dinner, amidst a scene of truly Gallic enthusiasm, the chairman announced that he had received a message from the President of the Republic commanding him to bestow the Grand Cross and the Insignia of a Commander of the Legion of Honour on his distinguished guest, and there was such applause consequent on the act that Sir William Broadbent's reply could scarcely be heard.

We have already alluded to several of Broadbent's contributions to literature and do not propose to give a complete bibliography, but we may mention a few more of the most important of his writings, viz.: "Theory of Construction of the Nervous System," "Structure of the Cerebral Hemispheres," "Mechanism of Speech and Thought," "Ingravescent Apoplexy," "Angina Pectoris," "Adherent Pericardium," "The Application of Chemical Principles in the Action of Remedies and Poisons," "Arterial Pressure in Bright's Disease," "The Remote Effects of Remedies," "Word-Blindness and Memory," "Vascular Tension," "Adherent Pericardium," "Myoidema," "Peritonitis," "Blood Pressure," "Aphasia," and others, many of which appeared in the columns of this journal.

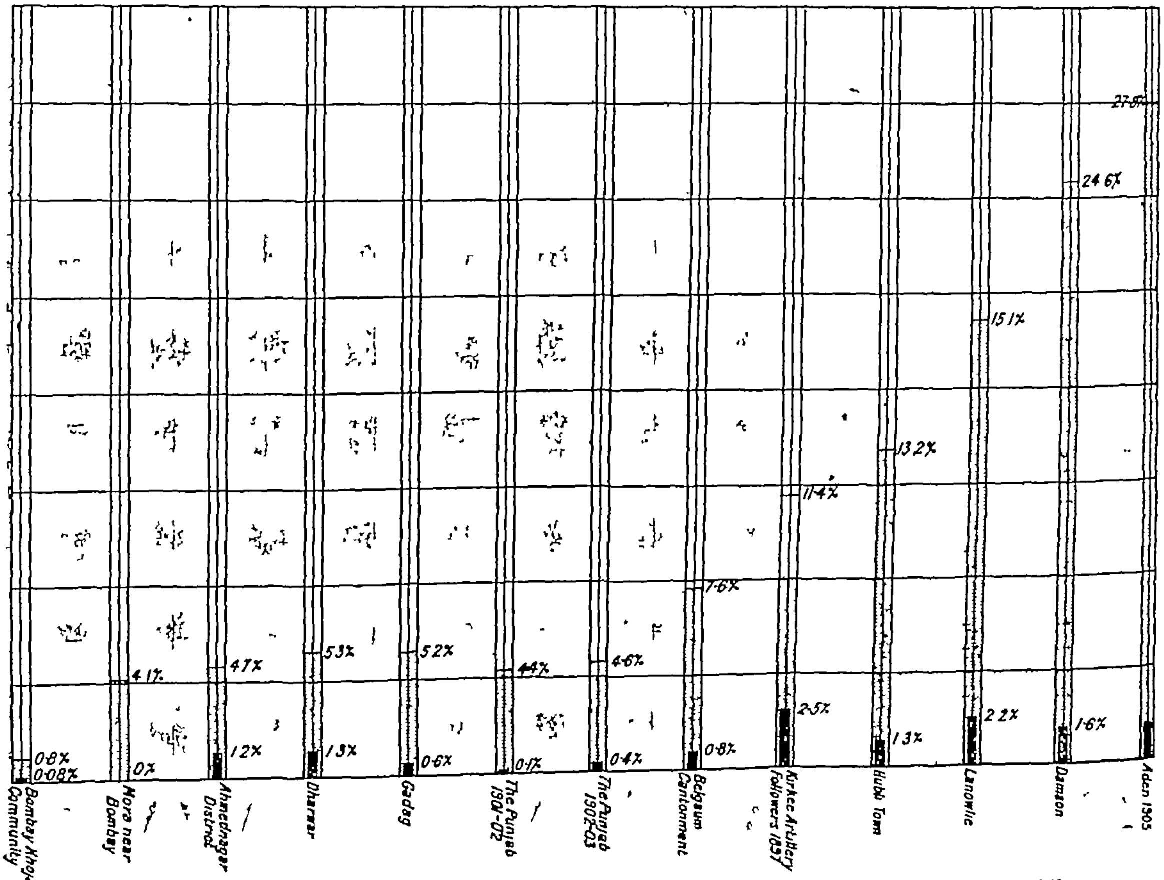
The following appreciation of Sir William Broadbent as hospital teacher and member of a hospital staff is from the pen of one of his colleagues at St. Mary's Hospital:—

"It is some ten years since Sir William Broadbent gave up active work at St. Mary's Hospital, but those who have since succeeded him as members of the staff are for the most part his old pupils and they with his former colleagues deeply lament his death. For Sir William Broadbent made the interests of St. Mary's Hospital his interests and there was no movement initiated for the good of hospital or school into which he did not enter with enthusiasm and which did not receive his active support and encouragement. Busy as he was, he ever found time to attend the board of management whenever any matter of importance came up for settlement. He was one of those who provided the residential college for the students of St. Mary's Hospital, and he gave the first of a series of those post-graduate lectures which, instituted at St. Mary's, have become permanently established in London, and it was greatly due to his efforts that the enlargement of the hospital and the addition of the Clarence wing were due. At the various social gatherings and entertainments connected with hospital life, notwithstanding the many calls upon him, Sir William Broadbent always found time to be present, not as a duty but as one who enjoyed them, and brought pleasure to others by his genial presence. Throughout a busy life he never, unless actually away from town, omitted his regular visits to the wards, and it was there that the fruits of his thoughtful labours, more especially in connexion with diseases of the circulation and of the nervous system, were made manifest to those who accompanied him. For his clinical instinct, his delicacy of touch, his grasp of a case, and his remarkable powers of diagnosis were more than marked—they were impressive. Sir William Broadbent at his best was rivalled as a clinician by few in London or anywhere else. Unlike many who devote care to diagnosis, he did not consider he had done his work when he had made his diagnosis, but to the treatment of the case there was always given much care and consideration. As a teacher Sir William Broadbent was not one of those who by rhetorical art and fluent expression attracted large numbers of the type of students whose ambition is to pass their examination without acquiring more than the bare minimum of knowledge; these he did not seek to attract, nor was his teaching of the level of the text-book routine or of the tutorial style, but at the bedside he was ever ready to instruct those who wished to excel and to appreciate those minuter points in the examination and observation which made Broadbent one of the select few. No one privileged to watch his work in the wards could be anything but impressed with his powers of observation and his refinement in diagnostic skill. He was ever fresh in mind, anxious to hear and to give weight to the observations of others, and ever ready

[Professor Simpson here showed upon the screen several diagrams dealing graphically with these figures. In Diagram I. A the *most instructive epidemics* had been taken which illustrated different degrees of severity on the population, the incidence of plague varying from 1·2 to 59·4 per cent. of the population. *The columns were formed on the* principle of each column representing 100 inhabitants inoculated or not inoculated.

Diagram I. A showed that the observations were made in epidemics in which the incidence of *attack* in the non-inoculated varied from 1·2 to 59·4. The incidence of attack among the inoculated varied from 0 to 11·3. In general the incidence of attack on the inoculated corresponds to the severity of the epidemic, but this is not uniformly the case, for in a few the inoculated show a striking immunity in the midst of very severe epidemics.

Diagram I. D represented the percentages of plague attacks averted by inoculation. Each column represented 100 attacks which occurred among the uninoculated population; the upper shaded portion of the columns represented the number of attacks which occurred in an equal number of the inoculated population. The remaining blank portion of the column shows the percentage of attacks averted by inoculation; the saving in attacks varies from 58 3 to 100 per cent. In the Jewish community in Aden *against* each 100 attacks among the non-inoculated there were *31·7* in the inoculated and the saving in cases was 68 3, whereas in the tailors' camp at Broach the inoculated escaped attack altogether and the saving was 100 per cent.



Inoculation on a large scale. *Percentage of plague deaths* to population. The stippled portions of the columns represent the percentage of deaths in the non inoculated. The black portions represent the percentage of deaths among the same number *of* inoculated.

The second class of observations, which represented observations of the working of the system on a large scale, furnished results similar to those obtained *on the smaller* scale. Table B gave those results. Of these Professor Simpson specially referred to the observations at Kirkee in 1897, because he had the opportunity, along with Haffkine, of checking the results on the spot. Of the community on which the experiment was made, 859 were not inoculated and 671 were inoculated. Out of the 859 not inoculated there occurred 143 cases with 98 deaths, and the proportion of deaths to cases was 68·5 per cent. Out of 671 inoculated there were 32 cases *with* 17 deaths and the proportion of deaths to cases was 53·1 per cent. Thus the incidence of attack on the not inoculated was 16·6 per cent. and of deaths 11 4 *per cent., whereas the incidence of attack* on the inoculated was 4 8 per cent. and of deaths 2·2 per cent. Or, in other words, there was among the inoculated a percentage of saving in cases of 71·4 and of deaths of 77·9, as compared with the not inoculated.] He went on to say:—

Undhera village *may also* be taken as another example. In this village more than half the population was inoculated, 513 being inoculated and 437 not being inoculated. Out of the 437 not inoculated there were 27 cases of plague with 26 deaths, the proportion of deaths to cases being 96·5 per cent. Out of the 513 inoculated there were eight cases with three deaths, the proportion of deaths to cases being 37·5 per cent. The incidence of attack among the not inoculated was 6·2 per cent. and of deaths 5·2 per cent., while among the *inoculated* the *incidence of* attack was 1·6 per cent. and of deaths 0·6 per cent. So that among the inoculated the percentage of saving in cases was 74·8 and in deaths 90 2, as compared with the not inoculated.

Considering the observations as a whole in the different places recorded the results show that the non-inoculated part *of the* population had between 4·3 and 34·9 per cent. *of* cases and between 0·8 and 27·9 per cent. of deaths, with a proportion of deaths to cases varying between 60·1 and 96·3 per cent., while the inoculated part of the population had been 0 4 and 4 8 per cent. of cases and between 0 and 2·5 per cent. of deaths, with a proportion of deaths to cases varying between 0 and 53·1 per cent. The number of cases among those inoculated was reduced *by between 52·2* and 94 per cent., and the number of deaths between 75·7 and 100 per cent, as compared to the incidence of attacks and deaths among the non-inoculated *inhabitants* of the same localities.

The following diagrams refer to the observations on large

Physics and Chemistry.—Arthur A. Campbell and Kenneth C. MacNaught.

AWARDS.

Medical travelling prize: Robert E. Wright. Medical scholarships: Anatomy and institutes of medicine—Adams A. M'Connell (Trinity) and Thomas A. Hughes (Stewart). Physics, chemistry, botany, and zoology—Henry J. Smyly (Trinity) and Herbert de L. Crawford (Stewart). Purser medal in institutes of medicine: Charles M. Finny.

DONATIONS AND BEQUESTS.—Under the will of Mr. John Doyle Fry £1000 are bequeathed to the North-Eastern Hospital for Children to endow a "John D. Fry Cot."

IN the presence of a large gathering the Mayor of Falmouth on July 5th formally opened the new winter gardens which have been provided by the corporation for the town.

MEDICAL MAGISTRATE.—Mr. David Livingstone Davies, L.R.C.P. Lond., M.R.C S. Eng., of Criccieth, North Wales, has been placed on the commission of the peace for the county of Carnarvon.

ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY, WIGAN.—Mr. W. Mitchell Roocroft, honorary surgeon to the institution, has been re-elected chairman of the board of management of the Wigan Infirmary for the ensuing year.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—At Cardiff on June 28th the members of the class of the St. John Ambulance Association, held in connexion with the Cardiff branch of the National Union of Teachers, presented Miss Erie Evans, M.B. Lond., L.S.A., with a hypodermic syringe, and Mr. Alfred Howell, M.D. Lond., L.R.C.P. Lond., M.R C.S. Eng., with an auroscope in appreciation of their services as honorary lecturers.

THE PLUMBERS' COMPANY.—At the quarterly court held at the Guildhall on July 6th the freedom of the Worshipful Company of Plumbers was conferred on W. G. Bishop, F. Dewhurst, A. Helsby, E. B. Sawyer, and W. Worthington, young plumbers from Cardiff, Ramsbottom, Leigh (Lancashire), Barry, and Blackpool respectively. They had passed, in honours, the Company's examination in workmanship and technical knowledge and the Master of the Company (Mr. W. D. Caröe), in addressing them on admission, reminded them that they were added to the Company's long roll of craftsmen which always included in earlier times, as at the present day, men distinguished among their fellows. He urged them, as new members of a very ancient body, to respect its best traditions and to realise the growing responsibility of plumbers to safeguard for the public the sanitary and water services that become more complex with the growth of towns, and consequently demand higher craftmanship, as well as closer coöperation between those who represent the plumbing craft and those whose official and professional duty it is to act for the public in framing regulations and specifications relating to plumbers' work. "The Company's mission," he said, "was to extend the principle on which the guild was founded—namely, that craftsmanship and citizenship should go hand in hand. The citizen should recognise and respect the craftsman and the craftsman should remember the duty which he owes to the citizen to give him good work."

PROFESSOR OSLER ON WOMEN DOCTORS.—Professor William Osler, in the course of an address delivered to the students of the London (Royal Free Hospital) School of Medicine for Women on July 4th, observed that women were specially adapted for work in connexion with diseases of women and children, but the trouble was that women did not believe in women and this mistrust was one of the serious problems concerning the progress and evolution of women. One of the most important things for the students to do was to so conduct their lives that other women would have trust in them. On the whole, he considered that medicine was a satisfactory profession and satisfactory for women, but if they entered it with the idea that they were going to get a return in pounds, shillings, and pence for everything they did, they would be making the greatest mistake. People had long learned to look upon the medical profession as something far higher than a mere money-getting affair. An excellent field of work for women was offered in the studies connected with the higher problems of scientific medicine and there were good careers in laboratory work open for women in many parts of the world. Institutions and asylums afforded a line of work for women and he would like to see women physicians connected with every asylum for the insane in the country. General practice was beset with so many hardships that he advised the students to take serious counsel with their teachers, especially those who had been in general practice, before entering upon that work. In India there was ample opportunity for women and he recommended them to consider it favourably.

UGANDA PROTECTORATE.—According to the Blue-book for 1905–06 just presented to Parliament Uganda progresses in prosperity, education, and methods of local administration. It has now reached the advanced stage when the rate of progress is bound to be steady and it exhibits all the evidence of being continuous. No complete census has yet been taken. The estimated population is about 4,000,000 but this is probably too low. 2319 Christian, native, and Mahomedan marriages were celebrated during the year. Amongst Europeans there were two marriages, 12 births, and four deaths. The registration of births and deaths of natives is not yet made compulsory. The medical department is amalgamated with East Africa and is under the charge of Lieutenant-Colonel J. Will, R.A.M.C., who is assisted in Uganda by one senior medical officer and ten medical officers. Six medical officers were also appointed to assist in the new extended scheme for the investigation of sleeping sickness, and four of these have already arrived. The total cost of the medical department was £16,180. The principal medical officer reports that the health of Government officials has been good. Better sanitation, better houses, with the addition of mosquito-proof doors and windows, and extensive clearing operations in the forest and jungle near many of the principal stations have been mainly responsible for this. Three deaths have occurred among European officials—two from injury and one from malaria. Seven officials were invalided. The commonest diseases among officials were malaria, tick fever, and diseases of the digestive organs. One official has contracted sleeping sickness. Among Europeans, official and non-official, 228 have come under treatment for various diseases, fever being the cause in about half the cases. There were three cases of blackwater fever during the year, with no deaths. It is difficult to form an opinion as to the general health of the native population, as only those in the immediate vicinity of the Government stations come in for treatment. Sleeping sickness, though on the decline in some districts, is very prevalent in others and still claims its thousands of victims. 113 natives are known to have died from small-pox. Venereal disease is also very rife. The health of the troops and of the police has been satisfactory. As to sleeping sickness, there was, unfortunately, nothing new in the way of treatment or prevention to report. Taking into consideration the numbers that have fallen victims to this disease in Usoga and North Kavirondo and the reduction in population already caused by it there is reason to believe that it is dying out in these two districts. During the end of the year a scheme of extended investigation of the disease was formulated and six medical officers were appointed to carry out this work. Their investigations up to Dec. 31st were of a preliminary nature and it will take some time before any practical result can be looked for. Each medical officer has been appointed to a district in which the disease is known to exist and the lines of investigation have so far been with the object of defining exactly the tsetse fly areas and the area in which locally infected cases are found, also of studying the habits of the fly. It will be very important in this investigation to win first the confidence of the natives. At Entebbe the most important sanitary measures carried out during the last year have been the provision of mosquito-proof doors and windows to a great many of the houses, extensive clearing operations in the forest and jungle in the vicinity, and the filling in of a large number of cesspools and other places where water used to collect. The new attempt to supply Entebbe with good water by means of two windmills and tanks has proved to be inadequate for the expanding requirements. Something like a small pumping station outside Entebbe, with a delivery tank placed in the centre of the town, would, perhaps, better meet the case. At Jinja better houses have been built and extensive bush-clearing has been carried out. During the year new offices and bath-rooms have been fitted to the large European hospital at Entebbe. The native hospital has been

A COMMON SPORADIC SEVEN-DAY FEVER OF INDIAN PORTS SIMULATING DENGUE.[1]

BY LEONARD ROGERS, M.D. LOND., F.R.C.P. LOND.,
MAJOR, I.M.S.; PROFESSOR OF PATHOLOGY, MEDICAL COLLEGE, CALCUTTA.

IN order to ascertain what proportion of the fevers in Europeans in Calcutta are malarial and if any other short fevers commonly occur there I have examined blood slides taken on admission before any quinine was given and kept notes and charts of every fever case in the large European Hospital for two complete years, 1350 consecutive cases being thus worked out. Commencing in the middle of September I found that almost all the short fevers for the first seven months—that is, up to the end of April—showed malarial parasites in their blood, although even the malarial cases had become very few since the end of January. In May, and still more from June to September, fevers of short duration began to increase once more, but now malarial parasites were conspicuous by their absence, and it soon became clear that the type and symptoms of the fevers then seen were quite different from the malarial series and more closely resembled in their general characters influenza and dengue (Diagram I).

DIAGRAM I.

The seasonal influence of seven-day fever compared with that of malaria.

During the following year of 1906 a similar, but shorter, prevalence was again noted, while an examination of the hospital records for several previous years showed that this fever always appeared at about the same time in greater or smaller numbers year by year, while its seasonal incidence was quite distinct from that of true malarial cases. I published a short account of this newly separated fever in the *Indian Medical Gazette* for November, 1905,[2] and dealt with its seasonal incidence and differentiation from malaria in the same journal in March, 1906, since which I have had much further experience of the disease and studied both its distribution in India and the literature of allied affections and so am anxious to bring it up for discussion by this society.

CLINICAL DESCRIPTION OF SEVEN-DAY FEVER.

Onset.—The onset of the fever is almost invariably found to be quite sudden and frequently to commence with chilliness and not rarely with a rigor, which in a few exceptional cases may recur, but not with the regularity of a true malarial fever. I have known a hospital patient convalescent from some other disease to be suddenly attacked with seven-day fever while out for a drive, his temperature being found elevated on his return. The onset is thus more sudden than is usual in typhoid fever.

Appearance on admission.—I shall show that about half the cases of this fever seen in Calcutta were admitted during the terminal rise about the fourth or fifth day of the fever, but in those who come in an early stage or are attacked while in hospital, the following points may be noted. The face was usually flushed and the conjunctiva presented a vivid red appearance, while the general expression was often dull and listless and highly suggestive of early typhoid fever, and in several cases the addition of some abdominal pain and a few suspicious spots gave rise to such a strong suspicion of that disease that a Widal test was performed with a negative result, which was soon confirmed by the early cessation of the fever. Moreover, I have frequently seen such typhoid-like cases in consultation and I regard their occurrence as a point of great importance in separating this sporadic seven-day fever from epidemic dengue, which it closely simulates in some repects, for I can find no description of typhoid-like cases in dengue, although they could not well have been overlooked in that disease if the two fevers are one and the same.

Headache.—Severe headache, almost invariably frontal, is one of the most constant symptoms accompanying the onset of the fever, often together with pain in the back of the eyes, so that when asked to point out exactly where the pain is felt the patient places his forefinger and thumb one on each side just behind the external orbital processes of the frontal bone. The headache in malaria is less frequent and more variable in position than that of seven-day fever.

Pains in the back and limbs.—In addition to headache, pains in the back, and only slightly less frequently in the limbs as well, are almost constantly present, while occasionally they are described as occurring in the joints, but without any local swelling or tenderness. They generally come on suddenly with the initial fever and may be sufficiently severe to disturb the night's sleep, but according to several medical men with a personal experience of both seven-day fever and dengue (who expressed their opinions at a discussion on the subject at the recently instituted Medical Section of the Asiatic Society of Bengal), the pains in the sporadic fever are nothing like as severe and intractable as those of true epidemic dengue. They more closely resemble those of influenza and are more constant and severe than the aching pains of malarial fevers.

Alimentary system: tongue.—Another very characteristic feature is the appearance of the tongue, the dorsum being furred, often markedly so, while the edges are raw and red, and a "strawberry" appearance may be seen. This condition is in marked contrast to the uniform slight furring usually met with in malarial fevers, but, on the other hand, it resembles that of influenza and dengue from which the diagnosis may be equally difficult.

Sickness.—This symptom was not frequently recorded, much less so than in malaria, so its absence is a point in the differential diagnosis against the latter disease.

Bowels.—There were no constant features regarding the bowels, which were usually regular, while constipation and slight looseness were about equally frequently met with in the remainder. Pain in, or slight distension of, the abdomen was also occasionally noted.

The liver.—Very rarely was the liver slightly enlarged and no symptoms referable to derangement of this organ were met with.

The spleen.—This organ was very rarely enlarged, and then only to a slight degree, so that increase in the size of this organ is in favour of malarial as against seven-day fever.

[1] A paper read before the Royal Medical and Chirurgical Society on April 9th, 1907.

[2] Indian Medical Gazette, November, 1905.

age die annually from various forms of tuberculosis, he would nsider the advisability of the introduction by His Majesty's Governent of legislation to prevent the keeping of tuberculous cows on dairy rms.—Mr. BURNS replied to both questions in the following terms: am aware of the report referred to in the questions. As regards the first uestion I do not gather that it has been ascertained that the diseased eat of the cows mentioned in it has been disposed of in London, lthough London is stated to be the probable destination of many of he animals. I may point out that if any diseased animal or meat ntended for the food of man is exposed for sale it is liable to inspection nd seizure. The matters, however, to which the questions relate are eceiving my consideration.

Mr. BRAMSDON also asked the honourable Member for South Somerset, s representing the President of the Board of Agriculture, whether is attention had been called to statements in an official report of he medical officer of health of Portsmouth, to the effect that milch ows badly diseased with tuberculosis were systematically sold for uman food at certain country markets; and further, that these cows, hough almost dying from disease, had up to the time of their being xposed for sale been used for the supply of milk, whether he would ave the facts as stated investigated, and, if found correct, whether the Board of Agriculture would make an order, as empowered by the Diseases of Animals Act, 1894, making tuberculosis in animals the ubject of administrative action by the Board.—Sir EDWARD STRACHEY nswered: The attention of my noble friend (Earl Carrington) has been drawn to the report to which my honourable friend refers, but as it deals primarily with matters of public health he proposes to confer with the President of the Local Government Board before taking any action thereon.

Meat Inspection in Scotland.

Mr. WATT asked the Secretary for Scotland if he would state what sums the following county local authorities paid in 1906, or 1905 if the later date was not available, for inspecting and supervising the slaughter of animals within their jurisdiction; whether, and in what cases, these sums were paid to veterinary surgeons or to medical practitioners; and what number of carcasses, if any, were condemned in these various counties as unfit for human food—viz., Renfrew, Dumbarton, Stirling, Ayr, Linlithgow, Lanark, and Peebles.—Mr. SINCLAIR replied: It is impossible to state for any of the counties named the sums paid in any year for inspecting and supervising the slaughter of animals. Such inspection and supervision as a rule forms part of the duties of the officers of the Public Health Department, more especially the sanitary inspectors. Such officers are paid inclusive salaries and it is impossible to state exactly the amount paid in respect of the above mentioned duty. As regards the last part of the honourable Member's question, 35 carcasses were wholly condemned and internal organs and parts of 357 other carcasses were condemned during 1906; of these carcasses, one was condemned in Dumbartonshire, one in Stirlingshire, and the remainder in the upper middle wards of Lanarkshire. None were condemned in Renfrew, Linlithgow, Ayr, or Peebles. I may explain that in the counties other than the upper middle wards of Lanarkshire a considerable proportion of the meat consumed is supplied from the public slaughter-houses situated within the burghs. For example, I am informed that in the lower ward of Lanarkshire almost the whole of the meat is obtained from Glasgow.

MONDAY, JULY 8TH.

The Consolidation of the Public Health Acts.

Sir IVOR HERBERT asked the President of the Local Government Board whether, having regard to the inconvenience experienced by local authorities in the administration of the Public Health Acts, from the fact that the law had to be sought in a large number of public Acts, and in some cases was affected by private Acts of Parliament, he could hold out any hope of bringing in a Bill next year to consolidate all enactments bearing upon the public health and to confer equal powers in respect thereto on all local authorities.—Mr. BURNS replied: I am afraid that it would not be practicable to confer equal powers in respect of public health on all local authorities. This would involve an undue interference with special powers conferred by local Acts. Moreover, powers which might properly be conferred in respect of one district would not always be suitable to another of a different character. I realise the advantage there would be in consolidating the Public Health Acts, though I think it would probably be found necessary in the first instance to amend them in some respects. I cannot give any pledge as to legislation for next year, but I shall be glad when opportunity offers to take steps in the direction indicated.

The Sanitary Condition of Lewis.

Mr. WEIR put a series of questions regarding the sanitary condition of the Island of Lewis to the Secretary for Scotland.—Mr. SINCLAIR replied that the local authority in the island was already raising and expending the full amount of its public health rate. However, he hoped to find means to enable it to do more in this respect. The whole question had his close attention.

Mr. REES: Arising out of the insanitary character attributed by the honourable Member to his constituency, may I ask the right honourable gentleman whether he will consider the advisability of lending to the Ross-shire county council the services of the medical officer for Colwyn Bay?—No answer was given.

Scarlet Fever in Stornoway.

Mr. WEIR asked the Secretary for Scotland whether he was aware that at a recent meeting of the Stornoway town council public health sub-committee a letter was read from the medical officer stating that there was reason to believe that there were many cases of scarlet fever in the town which had not been notified and that these cases were causing the spread of the disease throughout the community; and, in view of the insanitary condition of the Island of Lewis, as reported by Dr. F. Dittmar, the medical inspector of the Local Government Board for Scotland, would he state what steps the Stornoway town council was taking to prevent the spread of the scarlet fever epidemic throughout the island.—Mr. SINCLAIR said in reply: I am aware of outbreak referred to and the Local Government Board has been and still is in communication with the local authority as to measures taken to prevent the spread of disease. The disease was of so mild a type that it was mistaken for a simple sore-throat and a number of cases escaped notification. The junior and infant departments of the public school were closed and will remain so for a further period of three weeks from June 24th.

The Medical Officer of Lewis.

Mr. WEIR asked the Secretary for Scotland whether he was aware that, in defiance of the opinion expressed by the Local Government Board for Scotland that it was not possible for the duties attaching to the office of chief district medical officer in the Island of Lewis to be discharged by anyone resident in Dingwall, the Lewis district committee, at its meeting on June 26th, appointed a medical officer who was resident at Dingwall; and would steps be taken to see that the Board's views on the subject were not overriden by the local authority.—Mr. SINCLAIR answered: I am aware that the facts are as stated and the Board is considering what steps should be taken.

TUESDAY, JULY 9TH.

The Plague in India.

Mr. FIELD asked the Secretary of State for India whether he could state the total number of deaths in India from plague since it appeared, giving the number in each year; and what measures had been taken with a view of prevention.—Mr. MORLEY (by printed answer) replied: According to a return which the Government of India has lately issued the deaths are: 1896, 1704; 1897, 56,055; 1898, 117,953; 1899, 134,788; 1900, 93,150; 1901, 273,559; 1902, 577,427; 1903, 851,263; 1904, 1,022,299; 1905, 950,863; 1906, 332,181; 1907 (Jan. 1st to May 31st), 991,003; total, 5,402,245. The preventive measures which have proved most successful are (1) the systematic destruction of rats; (2) disinfection of houses and clothing; (3) evacuation of infected localities; (4) inspection of travellers; (5) segregation of the sick; and (6) inoculation. I hope shortly to lay papers upon the table which will give a fuller account of the policy of the Government of India.

Medical Officers and Veterinary Surgeons in Ireland.

Mr. SLOAN asked the Chief Secretary to the Lord Lieutenant of Ireland whether, in view of the fact that public bodies usually took the opinion of veterinary surgeons in preference to medical officers of health on questions of post-mortem symptoms and clinical appearances, he would in introducing any future legislation on such matters secure to them the same position as that held by veterinary surgeons under the Public Health Acts of Scotland.—Mr. BIRRELL replied: The suggestion contained in the question will be duly considered when further legislation in regard to public health is in contemplation.

The Preservation of Foods.

Mr. CARR GOMM asked the President of the Local Government Board whether he was aware that borax and boric acid were largely used in the United Kingdom for the preservation of ham, bacon, milk, and other articles of food; whether their use for this purpose was permitted in the countries exporting such articles of food to the United Kingdom; whether, to be effective, the borax or boric acid must penetrate the article treated; whether, if so, any deleterious effect could be prevented by superficial washing; and whether he intended to introduce a measure forbidding the application of such preservatives to articles of food intended for consumption in this country.—Mr. BURNS, in a written reply, answered: I am aware of the facts as regards the use in the United Kingdom of borax and boric acid for the preservation of certain articles of food and that in some countries from which such articles are sent here the use of these preservatives is prohibited, although in certain of these countries the prohibition does not extend to foods prepared for export to the United Kingdom. If boron preservatives are used for packing such articles of food as hams and bacon they usually penetrate the substance of the meat and would not be removeable by superficial washing, whilst penetration must, of course, occur if solutions containing these preservatives are used for pickling or injection. The Public Health (Regulations as to Food) Bill which I have introduced, and which is now before the House, would enable the Local Government Board to make regulations for the prevention of danger to public health from the importation, preparation, and storage of articles of food intended for human consumption, and thus to deal with the matter referred to in the question.

WEDNESDAY, JULY 10TH.

The Destruction of Carcasses of Tuberculous Pigs.

Mr. SILCOCK asked the President of the Local Government Board whether his attention had been drawn to the losses which were being incurred by the farmers of this country owing to the number of carcasses of tuberculous pigs which were being destroyed by order of the medical officers of health without any compensation being paid to the owners; whether he was aware that in the majority of cases there was no indication that a pig was suffering from tuberculosis until an examination of the carcass was made; and whether he was now prepared to bring in a Bill to provide that some compensation should be given to farmers for the losses which they sustain when animals which had been apparently healthy were destroyed in the interests of the public health.—Mr. BURNS replied: I am aware that carcasses of tuberculous pigs are destroyed and this involves loss to the owners. I am also aware that in some cases the disease is not recognisable during the life of the animals; but this is not always so, and it must not be assumed that the cause of the disease is necessarily not preventable. I cannot promise to introduce a Bill for the purpose suggested.

been almost invariably returned in the different parts of India where this fever occurs. Nevertheless, the fever has a *most characteristic* temperature curve, best described by the term "saddle-back," which it will be well *to show first*, and then to return to the variations from this typical course.

The typical saddle-back temperature curve.—Chart 1 shows the characteristic temperature curve from beginning to end. The temperature, which was taken every four hours, rose rapidly to over 105° and was very little reduced by repeated spongings (as shown by the dotted lines in the chart). It gradually declined during the next two days to about 100°, at which point it remained steadily for three days before the characteristic terminal rise carried it up again to 103° and was succeeded by the final fall occupying 24 hours. The pulse was markedly accelerated during the unusually high first rise of the temperature, but during the terminal one it is noteworthy that it was not found to reach over 82 beats a minute with a pyrexia of 103°.

Chart 2 is a two-hour curve showing how continued the fever was between 100° and 102° before the typical terminal rise. The pulse in this case was never recorded as above 100 and never reached even 80 during the terminal rise, in spite of the temperature attaining to over 103°, a most characteristic feature of this fever. In fact, up to the sixth day the pulse and temperature curve might have been those of typhoid fever, except that in my experience such a saddle-back remission to as low a point as 100° is rare in the early stage of typhoid fever once a higher point has been reached.

Chart 3 again shows the same saddle back type but with a still more marked remission to reach 99°, and a final rise once more to 103°, accompanied by a pulse never exceeding 100 per minute, except immediately after admission.

One step more to a complete remission of the temperature to the normal point and we arrive at a case in which the pyrexia ceased for two complete days and yet the terminal rise to 103° occurred before the final fall to normal. Such a complete remission as this is exceptional, for in five-sixths of my cases, patients admitted within the first few days, the temperature never fell below 99° during the usual remission, while in considerably fewer still did it actually reach the normal line, a point in which this seven-day fever differs most essentially from the three day pyrexia ending by crisis of true epidemic dengue.

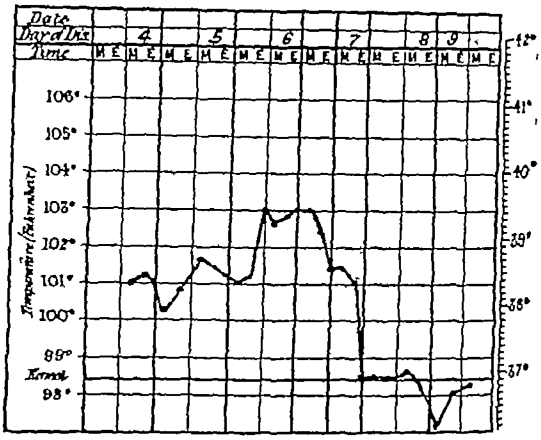
Continued typhoid-like group.—Although the saddle-back temperature curve is by far the most characteristic and frequently met with type in patients admitted in the early days of the fever, still there may be considerable variations from this form, the most important of which is the continued type simulating the early stages of typhoid fever, for the latter disease by no means very rarely begins fairly abruptly and without the classical step like rise in cases in tropical India Chart 4 is one of the most marked examples of this form I have met with, although I have a number of charts showing an equally continued fever but usually at a slightly lower level. These continued cases frequently give rise to needless fear of typhoid fever, but the symptoms already described will, as a rule, allow of a correct diagnosis being arrived at after some experience of the disease. In several private cases, in which I was asked to examine the blood for typhoid fever, I have been able to recognise the fever clinically and correctly to assure the friends that the temperature would fall on the sixth or seventh day.

In another patient attacked while in hospital the high initial rise was less abrupt than usual, so that the terminal one showed the highest point of the pyrexia, but with a slow pulse; a less common type which may also give rise to a suspicion of typhoid for several days. The opposite condition also occurs, quite exceptionally, in which the terminal rise is completely absent, although the temperature may not finally reach the normal until the sixth day.

Terminal cases.—I have already mentioned that just about half these patients only come to hospital during the terminal rise of temperature, and this is easy to understand when we remember that in a large number of the cases the pyrexia falls to about 100° or under on the second or third day, accompanied by a remission of the severe headache and pains in the back and limbs, so that the patient thinks he is rapidly getting over his trouble. It is only when he is rudely awakened from this happy frame of mind by the second rise of temperature that he comes into hospital for treatment, where his fever rapidly ceases while taking the inevitable quinine, so that both he and his medical attendant usually have no suspicion that he has suffered from anything but an attack of malaria.

In another patient admitted on the third day the temperature fell to almost normal on the following day, after which a well-marked terminal rise took place, during which the temperature remained persistently at about 104° for over 24 hours in spite of frequent spongings, which had only a very ephemeral effect on the pyrexia. The pulse was also never recorded as rising over 92 during this high temperature, while a very slight and short recrudescence of fever occurred just after the cessation of the secondary curve, as is rarely the case. Chart 5 is that of a man admitted on the fourth day with a low continued type of fever succeeded by the characteristic terminal rise with a slow pulse. In another unusually short case admitted at about the beginning of the terminal rise, the fever only lasting two days under quinine, but with the slow pulse of seven-day fever and not the rapid one of malaria. In this case, as in every one on which this paper is based, a blood film taken before any quinine had been administered in hospital was examined for malarial parasites with a negative result.

CHART 5.



Case admitted on the fourth day showing terminal rise.

These last mentioned three cases will serve to illustrate the very frequent admissions during the terminal rise of pyrexia, many of them only coming to hospital on the fifth or sixth day of the disease but a few hours before the final fall. In such only the history of the patient, the absence of malarial parasites, and, above all, the slow pulse during high fever, aided by their occurring in the regular season for this disease, will allow of a correct diagnosis being arrived at and the common error of returning them as malaria avoided.

THE DURATION OF THE FEVER.

On account of the patients coming to hospital in any stage of the disease the actual duration of the fever after admission varies widely from one to eight, or rarely over eight, days. The total duration of the fever in just about three-quarters of them was either six or seven days, so that the temperature either fell to normal on, or finally remained normal during, the seventh day in this proportion, and hence the name of "seven-day fever" which I have proposed for the disease. A slightly larger number of cases end on the sixth than on the seventh day, but it appeared to me to be better to take the later day for the name of the affection so as not to lead to its termination being expected at an earlier date than actually occurs in almost half the total cases. The following table shows the number of cases which terminated on different days of the fever, the cases denoted "typical" being those admitted sufficiently early to show the characteristic saddle-back or complete terminal rises of temperature, while the "terminal" cases are those admitted near the end of the disease, and so especially liable to be returned as malaria.

It will be seen from this table that in no case did the fever last less than three days, while in only four, or 2 per cent., did it end on the third day, all these being terminal cases in which the history of the duration of the fever before admission may have been inaccurately given. Further, in only eight cases, or 4 per cent., it ended on the fourth day, so that in the remaining 94 per cent. the fever lasted five or more days and in 86 per cent. it lasted six or more days—a

LIVERPOOL INFIRMARY FOR CHILDREN.—House Surgeon. Salary £100 per annum, with board and lodging.

LONDON HOSPITAL, Whitechapel, E.—Surgeon-Dentist.

MIDDLESEX HOSPITAL, W.—Medical Officer and Registrar to the Cancer Department. Salary £100 per annum, with board and residence.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—Clinical Assistants.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—Junior Resident Medical Officer. Salary £80 per annum, with board, residence, and laundry.

NORTHAMPTON GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £90 a year, increasing to £100, with apartments, board, washing, and attendance.

NOTTINGHAM CHILDREN'S HOSPITAL.—House Surgeon (female) for six months. Salary at rate of £80 per annum, with board, residence, and washing.

ERTH ROYAL INFIRMARY.—House Surgeon. Salary £60, with board.

INCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Honorary Anæsthetist.

UEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone road, N.W.—Resident Medical Officer for Out-patient Department for four months. Salary at rate of £60 per annum, with board, residence, and washing.

OTHERHAM HOSPITAL AND DISPENSARY.—Senior House Surgeon. Salary £110 per annum, with rooms, commons, and washing. Also Assistant House Surgeon. Salary £80 per annum, with rooms, commons, and washing.

OYAL DENTAL HOSPITAL, Leicester-square, W.C.—Clinical Pathologist and Demonstrator on Bacteriology. Stipend £75 a year.

OYAL NATIONAL ORTHOPÆDIC HOSPITAL.—Honorary Assistant Anæsthetist.

OYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, S.E.—Junior Resident Medical Officer. Salary at rate of £40 per annum, with board and washing.

EAMEN'S HOSPITAL SOCIETY.—Assistant Physician. Also Assistant Surgeon.

OUTH SHIELDS, INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Junior House Surgeon. Salary £90 per annum, with residence, board, and washing.

TOCKPORT INFIRMARY.—Assistant House and Visiting Surgeon. Salary £80 per annum, with board, washing, and residence.

TOCKPORT UNION, STEPPING HILL HOSPITAL.—Resident Assistant Medical Officer. Salary £130 per annum, rising to £150, with apartments, rations, &c.

TOCKTON-ON-TEES, STOCKTON AND THORNABY HOSPITAL.—House Surgeon. Salary £180 per annum, with residence, board, and washing.

TOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill.—Junior House Surgeon. Salary £50 per annum, with board, apartments, and washing.

AUNTON AND SOMERSET HOSPITAL, Taunton.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry. Also Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

UNBRIDGE WELLS GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, gas, firing, and attendance.

EST BROMWICH DISTRICT HOSPITAL.—Senior House Surgeon, unmarried. Salary £110 per annum, with, board, residence, and laundry. Also Assistant House Surgeon, unmarried. Salary £75 per annum, with board, residence, and laundry.

EST HAM INFIRMARY, Whipps Cross-road, Leytonstone, N.E.—Medical Superintendent. Salary at rate of £700 per annum, with house, light, and coal.

he Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Shaftesbury, in the county of Dorset; at Stanley, in the county of Durham; at Sturminster Newton in the county of Dorset; at Kirkcudbright, in the county of Kirkcudbright; and at Rathdowney, in Queen's County, Ireland.

Births, Marriages, and Deaths.

BIRTHS.

ODGSON.—On July 2nd, at Sherburn House, Durham, the wife of G. S. Dodgson, M.B., of a daughter.

UIGAN.—On July 3rd, at Woodstock-road, Oxford, the wife of William Duigan M.A., M.B., of a daughter.

UNN.—On July 6th, at Kimberley, Notts, the wife of J. Cecil S. Dunn, L.R.C.P.E., of a son.

MARRIAGE.

AURENCE—DAVIES.—On July 6th, at St. Mark's Church, Hamilton-terrace, George Laurence, M.R.C.S., L.R.C.P., of Inchmery-road, Catford, S.E., to Olive Mary, elder daughter of F. Herbert Davies.

DEATHS.

DAVEY.—On July 5th, at Havering House, Abergavenny, Norris Fasham Davey, M.R.C.S., L.R.C.P., late of Romford, Essex, in his 68th year.

LEIGHTON.—On July 5th, aged 30, of typhoid, at the Royal Southern Hospital, Liverpool, Frederick Francis Leighton, M.B., St. John's College, Cambridge, Resident Pathologist, R.S.H., eldest son of R. L. Leighton, M.A., Chesterton, late of Bristol.

POWELL.—On July 3rd, William Hodgson Powell M.R.C.S., L.R.C.P., of York road, Lambeth, and Studley-road, Clapham, aged 62.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

COUNTRY IN TOWN.

THE second Country in Town Exhibition was opened last week at the Whitechapel Art Gallery, High-street, Whitechapel, by Mr. Lough, M.P., Parliamentary Secretary to the Board of Education. In many ways it is as good as, if not better than, the exhibition which was held last year but the charm which was then given to the exhibition by the live butterflies which flitted from flower to flower is absent. As an object lesson in the possibility of bringing some of the delights of the country into the town the exhibition must be a success and it is a pity that more exhibitions of the kind cannot be held. The exhibits from the various schools in the poor neighbourhoods of London are a credit to the teachers and give evidence that nature study is having a good effect upon the minds and artistic faculties of the children. Two of the exhibits which deserve special mention are the model recreation ground and the model backyard and garden. In the model recreation ground an effort has been made so to construct a public garden that it may be used for the purpose of educating children in the fullest sense of the term. In fact, it is "an open-air cure" applied to education. There are open-air nurseries, and beds are provided for children; they can learn to manage themselves, just as soldiers do their tents. Gardening is, of course, one of the chief features of the scheme, but there is provision for other kinds of work. For the mothers a quiet place is provided where they can bring their little ones to sleep in the sunshine while they themselves can be engaged in needlework or any other occupation. Baths are not forgotten, nor is the milk van. Miss A. C. Sewell, who has arranged and constructed the model, is to be congratulated on a well-thought-out plan full of admirable suggestions. The model back garden shows how the ordinary London back yard can be turned into a thing of beauty instead of the dirty disease-breeding space which it usually is. Not everyone, perhaps, can afford time to visit the exhibition, but every town dweller should obtain a copy of the catalogue, for it contains much interesting and useful information, such as lists of plants which will live in the air of towns, plants grown in London parks, the water fowl at Regent's Park, and the British birds that have been seen in that park. This catalogue can be obtained for a penny and the postage, but subscriptions, however small, will be gratefully received by the secretary and there is a danger that these most desirable exhibitions will have to be discontinued unless financial help is forthcoming. The exhibition, which is open from 12 noon till 9.30 P.M., will close on July 18th.

OBSTRUCTING THE HIGHWAY WITH A MOTOR-CAR.

To the Editors of THE LANCET.

SIRS,—In your note *re* Dr. R. H. Spencer and his motor-car there evidently was absolutely no "obstruction." Not being a solicitor I have not noted the cases and cannot give you chapter and verse, but I certainly have seen it decided that a trader's van may "obstruct" the roadway for a time sufficient to enable him to deliver goods. I would ask why that should be allowed if a medical man must not have his car in front of a house where he is visiting. The position is absurd, for he cannot take the car into the house with him. When out driving I have had horses frightened by flaring naphtha lamps on costermongers' carts, but these are not interfered with, and in many parts costermongers' stalls are an abominable nuisance and obstruction.

I am, Sirs, yours faithfully,

Prince of Wales-road, S.W., July 10th, 1907. A. PHILLIPS HILLS.

A COWRIE SHELL IN THE NASAL CAVITY.

To the Editors of THE LANCET.

SIRS,—The case of a "Displaced Tooth in the Nasal Cavity," having lain there for years, reported in THE LANCET *of* May 4th last by your Vienna correspondent, reminds me of a boy I treated about 19 years ago in the hospital at Saugor, C.P. He was brought to me for a very offensive discharge from one of the nostrils which had gone on for years—I think 14 or so. The cavity was quite blocked and the probe would not pass more than three-quarters of an inch and gave a grating sensation to the finger. Naturally a rhinolith was suspected. After having thoroughly syringed out the nasal cavity the hard substance was caught hold of by a pair of forceps and gradually loosened from its seat and removed. It looked like a calculus with a very rough exterior but after placing it in water and removing the shell it turned out, to my astonishment, to be a "cowrie" (karishell) of the size of a medium sized almond. The peculiarity of the case lies in the foreign body having remained inside the nose for 14 years without doing any serious mischief and being, in this respect, analogous to the case of your Vienna correspondent. Children generally push in all sorts of things into their nostrils (and ears) but they are generally taken out at once as they cause great pain and inconvenience.

I am, Sirs, yours faithfully,

Arrah, June 19th, 1907. A. P. GHATAK, M.B.

reaching the highest point in July and declining again to very few in September, the fall as usual taking place just before the main rise in the malarial curve. If, however, a curve of the incidence of both fevers together is worked out (as shown in a paper on Malaria in Calcutta in the *Indian Medical Gazette* of March, 1906), then a single curve is obtained with two maxima, the first due to the seven-day and the second to malarial fevers. It is not, therefore, surprising that both these fevers have been so long confused together and regarded as malarial in nature. The late Lieutenant-Colonel A. Crombie, I.M.S., may have been thinking of the seven-day fever now described when he stated that in his belief 75 per cent. of the fevers in Calcutta returned as malaria did not belong to that category.

Distribution in India.—An examination of the records of all the fever cases for two or three years in the large hospitals of Bombay, Madras, and Lahore showed this seven-day fever to occur at the two first places only, but I have not found any cases in Lahore or in the United Provinces. It is thus a common fever with a definite seasonal distribution in the large seaports of India, among which Rangoon should also be included, for Captain F. N. Windsor, I.M.S., has reported to me that it is commonly seen there at about the same season that Calcutta is attacked. It is too early to say that it does not occur inland, but it seems pretty certain that it is at least comparatively rarely seen far from the coast line.

THE DIFFERENTIAL DIAGNOSIS OF SEVEN-DAY FEVER:

From malaria.—Briefly the diagnosis of seven-day fever from malaria, with which it has been so long confused, can usually be made clinically by attention to the points described in my paper on the latter disease. The chief of these are the totally different temperature curve in the cases admitted early, the more severe frontal headache, the red edge to the tongue, the rash when present, and pains all over, the absence of enlargement of the spleen and of malarial parasites in the blood, and especially in the terminal cases, by the slow pulse-rate accompanying high fever.

From influenza.—In Calcutta I find that influenza cases occur mostly from January to March and disappear in the hot weather before the seven-day fever season commences and do not appear again until late in the autumn when the other disease is practically at an end. Further, the temperature curve is usually an irregular intermittent one and never shows the typical saddle-back type of the seven-day fever, while the latter is scarcely ever complicated with the inflammatory signs in the lungs and throat which were nearly constant in the Calcutta influenza of 1892.

From dengue.—A much more difficult question is its separation from dengue, for the seven-day fever resembles the latter in its sudden onset, the severe headache and pains, the characters of the tongue, the rash, when present, and, to some extent, in its seasonal incidence and its distribution; so much so that I find from an extensive examination of the literature of fevers in India that the typical seven-day fever has been described as dengue by Dr. Edward Goodeve, I.M.S., in Calcutta in 1853,[5] and by Staff-Surgeon P. W. Bassett Smith[6] in Bombay in 1897, in addition to a recent outbreak at the Mount in Madras. On the other hand, the fever now being described differs most markedly from the classical accounts of dengue epidemics, as well as from the two great Indian outbreaks of 1824[7] and 1872,[8] so much so, indeed, as to make me think that it is quite distinct from dengue. The main points of difference are shown in the accompanying table:—

Table of the Differences between Dengue and Seven-day Fever.

	Dengue.	*Seven-day Fever.*
Prevalence:	At long intervals in epidemic form attacking large proportion of residents.	Annually in sporadic form.
Distribution:	Specially attacks coast towns but spreads far inland.	Only known near the coast so far.
Race incidence:	Europeans and natives equally attacked	Very common in Europeans, comparatively rare in natives.
Seasonal incidence:	Mostly in hot months but may prevail in cold season (1872).	Prevails in hot and rainy seasons only.
Relapses:	Very common in same year as first attack.	Rare and not in same year as first attack.
Pains:	Very severe and breakbone in character.	Moderately severe as in influenza and not of breakbone character.
Joint symptoms:	Very common and characteristic.	Absent or only present as slight pain.
Convalescence:	Very tedious, lasting from one to three months, with persistent joint pains.	Rapid; no after joint pains.
Fever:	Lasts two or three days, falling to normal with crisis; occasional very short secondary rise: markedly remittent.	Five to eight or more days with typical saddle-back remission to 100° or 99° F. only; otherwise continued in type.
Pulse:	Rapid.	Slow, especially in terminal rise.

In a recent discussion on this subject at the medical section of the Asiatic Society in Calcutta my friend Captain Megaw suggested that the seven-day fever is but a sporadic form of dengue, but Lieutenant-Colonel G. F. A. Harris, I.M.S., Major D. M. Moir, I.M.S., and Mr. A. Caddy, who had each seen both dengue and seven-day fever, were all positive that the two diseases are quite distinct. Further, Major W. G. Pridmore[9] and Captain J. W. Cornwall, I.M.S., and Captain J. Catto, I.M.S., who had all recently seen epidemic dengue in Burma, Madras, and Singapore respectively, are also of the same opinion, which I share. As, however, I have never seen epidemic dengue I hesitate to pronounce a decided opinion on the subject.

One thing at least appears to be quite certain—namely, that the seven-day fever has existed as one of the commonest fevers of Europeans in Calcutta year by year for a long period. Yet it has passed quite unrecognised by many medical men with experience of true dengue, so if it be but a sporadic form of that disease the descriptions of dengue require to be completely rewritten. It appears to me to be more likely that it is a new fever, not previously differentiated, than that every writer on dengue has overlooked the most characteristic temperature curve of the disease which I have illustrated in the charts.

EXPERIMENTS ON PROLONGED PROTEIN FEEDING,

WITH SPECIAL REFERENCE TO THE THYROID GLAND AND THE OSSEOUS SYSTEM.[1]

BY DAVID FORSYTH, M.D. LOND., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN AND JOINT PATHOLOGIST TO CHARING CROSS HOSPITAL; SENIOR PHYSICIAN TO OUT-PATIENTS AT THE EVELINA HOSPITAL FOR SICK CHILDREN.

A CONNEXION between meat eating and the production of gout has long been maintained and attempts to induce the disease in animals and birds by prolonged protein feeding have been made from time to time. The most recent experiments in this direction were undertaken by Chalmers Watson who fed eight fowls on meat alone for periods ranging from four to 16 months. His results were recorded in a paper read before the Royal Medical and Chirurgical Society in 1904.[2] No condition suggestive of gout was found in any of the birds, but, on the other hand, alterations in the long bones and hypertrophy of the thyroid glands were described and attributed to the excessive meat diet. These changes were so remarkable that it was thought desirable to repeat the experiments. This has been done during the past two to three years and the object of the present paper is to record the results obtained.

EXPERIMENTS.

The experiments began in October, 1904. Two cocks, two hens, and a cockerel were obtained, but shortly afterwards one of the hens was accidentally killed, and during the remaining period four birds were under observation. Except in the matter of food every care was taken to place them in healthy surroundings. They were kept in a commodious run, part of which was indoors under cover protected from rain and wind and part out of doors facing south-west and enjoying ample sunshine. The cage was kept clean and constant supplies of gravel, dust baths, and fresh water were provided. The protein diet was not commenced at once but

LIVERPOOL INFIRMARY FOR CHILDREN.—House Surgeon. Salary £100 per annum, with board and lodging.

NDON HOSPITAL, Whitechapel, E.—Surgeon-Dentist.

DDLESEX HOSPITAL, W.—Medical Officer and Registrar to the Cancer Department. Salary £100 per annum, with board and residence

UNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—Clinical Assistants.

WPORT AND MONMOUTHSHIRE HOSPITAL.—Junior Resident Medical Officer. Salary £80 per annum, with board, residence, and laundry.

RTHAMPTON GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £90 a year, increasing to £100, with apartments, board, washing, and attendance.

TTINGHAM CHILDREN'S HOSPITAL.—House-Surgeon (female) for six months. Salary at rate of £80 per annum, with board, residence, and washing.

RTH ROYAL INFIRMARY.—House Surgeon. Salary £60, with board.

NCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Honorary Anæsthetist.

EEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone road, N.W.—Resident Medical Officer for Out-patient Department for four months. Salary at rate of £60 per annum, with board, residence, and washing.

THERHAM HOSPITAL AND DISPENSARY.—Senior House Surgeon. Salary £110 per annum, with rooms, commons, and washing. Also Assistant House Surgeon. Salary £80 per annum, with rooms, commons, and washing.

YAL DENTAL HOSPITAL, Leicester-square, W.C.—Clinical Pathologist and Demonstrator on Bacteriology. Stipend £75 a year.

YAL NATIONAL ORTHOPÆDIC HOSPITAL.—Honorary Assistant Anæsthetist.

YAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, S.E.—Junior Resident Medical Officer. Salary at rate of £40 per annum, with board and washing.

AMEN'S HOSPITAL SOCIETY.—Assistant Physician. Also Assistant Surgeon.

UTH SHIELDS, INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Junior House Surgeon. Salary £90 per annum, with residence, board, and washing.

OCKPORT INFIRMARY.—Assistant House and Visiting Surgeon. Salary £80 per annum, with board, washing, and residence.

OCKPORT UNION, STEPPING HILL HOSPITAL.—Resident Assistant Medical Officer. Salary £130 per annum, rising to £150, with apartments, rations, &c.

OCKTON-ON TEES, STOCKTON AND THORNABY HOSPITAL.—House Surgeon. Salary £180 per annum, with residence, board, and washing.

OKE-ON TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill.—Junior House Surgeon. Salary £50 per annum, with board, apartments, and washing.

UNTON AND SOMERSET HOSPITAL, Taunton.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry. Also Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

NBRIDGE WELLS GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, gas, firing, and attendance

ST BROMWICH DISTRICT HOSPITAL.—Senior House Surgeon, unmarried Salary £110 per annum, with, board, residence, and laundry. Also Assistant House Surgeon, unmarried. Salary £75 per annum, with board, residence, and laundry.

ST HAM INFIRMARY, Whipps Cross-road, *Leytonstone, N.E.*—Medical Superintendent. Salary at rate of £700 per annum, with house, light, and coal.

COUNTRY IN TOWN.

THE second Country in Town Exhibition was opened last week at the Whitechapel Art Gallery, High-street, Whitechapel, by Mr. Lough, M.P., Parliamentary Secretary to the Board of Education. In many ways it is as good as, if not better than, the exhibition which was held last year but the charm which was then given to the exhibition by the live butterflies which flitted from flower to flower is absent As an object lesson in the possibility of bringing some of the delights of the country into the town the exhibition must be a success and it is a pity that more exhibitions of the kind cannot be held. The exhibits from the various schools in the poor neighbourhoods of London are a credit to the teachers and give evidence that nature study is having a good effect upon the minds and artistic faculties of the children. Two of the exhibits which deserve special mention are the model recreation ground and the model backyard and garden. In the model recreation ground an effort has been made so to construct a public garden that it may be used for the purpo-e of educating children in the fullest sense of the term. In fact, it is "an open-air cure" applied to education. There are open-air nurseries, and beds are provided for children; they can learn to manage themselves, just as soldiers do their tents. Gardening is, of course, one of the chief features of the scheme, but there is provision for other kinds of work. For the mothers a quiet place is provided where they can bring their little ones to sleep in the sunshine while they themselves can be engaged in needlework or any other occupation. Baths are not forgotten, nor is the milk van. Miss A. C. Sewell, who has arranged and constructed the model, is to be congratulated on a well-thought-out plan full of admirable suggestions. The model back garden shows how the ordinary London back yard can be turned into a thing of beauty instead of the dirty disease-breeding space which it usually is. Not everyone, perhaps, can afford time to visit the exhibition, but every town dweller should obtain a copy of the catalogue, for it contains much interesting and useful information, such as lists of plants which will live in the air of towns, plants grown in London parks, the water fowl at Regent's Park, and the British birds that have been seen in that park. This catalogue can be obtained for a penny and the postage, but subscriptions, however small, will be gratefully received by the secretary and there is a danger that these most desirable exhibitions will have to be discontinued unless financial help is forthcoming. The exhibition, which is open from 12 noon till 9.30 P.M., will close on July 18th.

OBSTRUCTING THE HIGHWAY WITH A MOTOR-CAR.

To the Editors of THE LANCET.

SIRS,—In your note *re* Dr. E. H. Spencer and his motor-car there evidently was absolutely no "obstruction." Not being a solicitor I have not noted the cases and cannot give you chapter and verse, but I certainly have seen it decided that a trader's van may "obstruct" the roadway for a time sufficient to enable him to deliver goods. I would ask why that should be allowed if a medical man must not have his car in front of a house where he is visiting. The position is absurd, for he cannot take the car into the house with him. When out driving I have had horses frightened by flaring naphtha lamps on costermongers' carts, but these are not interfered with, and in many parts costermongers' stalls are an abominable nuisance and obstruction.

I am, Sirs, yours faithfully,

Prince of Wales-road, S.W., July 10th, 1907. A. PHILLIPS HILLS.

A COWRIE SHELL IN THE NASAL CAVITY.

To the Editors of THE LANCET.

SIRS,—The case of a "Displaced Tooth in the Nasal Cavity," having lain there for years, reported in THE LANCET of May 4th last by your Vienna correspondent, reminds me of a boy I treated about 19 years ago in the hospital at Saugor, C.P. He was brought to me for a very offensive discharge from one of the nostrils which had gone on for years—I think 14 or so. The cavity was quite blocked and the probe would not pass more than three-quarters of an inch and gave a grating sensation to the finger. Naturally a rhinolith was suspected. After having thoroughly syringed out the nasal cavity the hard substance was caught hold of by a pair of forceps and gradually loosened from its seat and removed. It looked like a calculus with a very rough exterior but after placing it in water and removing the shell it turned out, to my astonishment, to be a "cowrie" (karishell) of the size of a medium sized almond. The peculiarity of the case lies in the foreign body having remained inside the nose for 14 years without doing any serious mischief and being, in this respect, analogous to the case of your Vienna correspondent. Children generally push in all sorts of things into their nostrils (and ears) but they are generally taken out at once as they cause great pain and inconvenience.

I am, Sirs, yours faithfully,

Arrah, June 19th, 1907.

A. P. GHATAK, M.B.

outline of a squat cubical epithelium and some vesicles were lined partly by the flattened variety, partly by the squat cubical. There was no folding of the lining epithelium nor had any proliferation of the secreting cells occurred (Fig. 2). The *parathyroids* consisted of the usual clumps of polyhedral, embryonic-looking cells, the protoplasm of some being clear and of others oxyphile and granular. No detail that was not normal to the avine thyroid and parathyroid was present.

Pituitary gland.—All four pituitary glands showed the usual cellular structure but there was a remarkable increase in the quantity of colloid present in the bodies. Drops of this secretion were scattered to excess through every section.

No change was observed in any of the other viscera.

REMARKS.

All the birds thrived on the diet, increasing considerably in weight and laying down plentiful fat. It is difficult to say to what extent, if at all, the special feeding was responsible for the attack of diarrhœa. The illness did not appear until some weeks after the dietetic treatment had commenced, and although no modification was made in the character of the food the symptoms passed off and never returned. Poultry are known to be subject to epidemic attacks of diarrhœa[3]; on the other hand, it was noted as long ago as 1660[4] that "the flux in poultry commeth with eating too much moist meat." My impression was that the diarrhœa in these experiments was not directly attributable to the character of the food.

With a view to comparison with the above results Chalmers Watson's experiments may be briefly summarised. Eight fowls were dieted for from four to 16 months. Two died from "acute nervous derangements" at the fourth and seventh months respectively, and two at the end of six months were returned to the poultry yard in apparently perfect health. Of the four remaining, one (No. 4), which at the post-mortem examination was found to be tuberculous, gained in weight, the others (Nos. 3, 5, and 6) lost weight. The tuberculous fowl suffered an attack of paralysis shortly before death. Another fowl presented attacks of "paralysis" from which it recovered without any change in the *régime*. The two remaining birds—both cocks—showed motor symptoms, one being paretic, the other paralysed. In all there was a striking absence of the clinical features of gout. The post-mortem findings were as follows. The two fowls that succumbed at the fourth and seventh month respectively revealed no gross lesions. Their thyroid and parathyroid glands were not examined microscopically. Fowl No. 4 presented tuberculous ulceration of the ileum and a liver studded with caseous tuberculous nodules. Its thyroids were normal. Of the fowls Nos. 3, 5, and 6 the only changes common to all were found in the thyroid and parathyroid glands which were recorded as enlarged in Nos. 3 and 6 and enormously enlarged in No. 5. Histological examination showed (*a*) increase in size of vesicles which were filled with colloid, (*b*) diminution in intervesicular glandular tissue, and (*c*) increase in the number of cells in the walls of the vesicles. Sections of the parathyroids were normal. Changes in the long bones were observed in Nos. 3 and 6. The bones were increased in thickness and irregular on the surface and the femora were markedly curved. The marrow had almost entirely disappeared, being replaced by a fairly dense, non-cellular tissue presenting some of the characters of an osseoid tissue. A similar appearance was seen in the outer part of the bone and apparently represented much altered Haversian spaces. Chemical examination showed a great increase in the proportion of organic matter.

Comparing the results now being recorded with those above quoted, they will be found to agree only in the absence of any changes suggestive of gout. The following points may be specially emphasised: (1) There were no nervous or motor symptoms at any time; (2) the health of all four birds was excellent at the time they were killed; (3) the thyroid and parathyroid glands were not enlarged (*vide infra*) and their sections presented the normal features of the avine glands; (4) the shafts of the long bones were not increased in thickness nor were they irregular or curved; and (5) on the other hand there was a striking increase of colloid in the pituitary glands—organs not examined by Chalmers Watson. These results show that fowls fed for a long period on an exclusive protein diet and at the same time kept under healthy conditions, including a supply of lime and other bases, present no loss of weight, no changes in the thyroid or parathyroid glands, and no changes in the osseous system. The two most important points raised by the above observer are the changes in the osseous system and the hypertrophy of the thyroid glands.

1. *The changes in the osseous system.*—These have already been detailed but there is ample ground for declining to accept them as the result of excessive meat diet. The context provided shows that the changes should be ascribed to an insufficient supply of calcium and other bases. The necessity of supplying fowls with ample lime is recognised by all poultry keepers, and a deficiency of this material produces a condition known to them as "leg-weakness." Wright in his "Book of Poultry,"[5] which I am informed is a standard work on the subject, says that leg-weakness "may arise from ...... a deficiency of bone-matter; and the symptoms ...... consist of a more or less constant squatting on the ground instead of standing or walking." Chalmers Watson says of his birds that they "showed a great tendency to sit, and would rest on the ground for much longer periods than was natural." The possibility suggested by Wright's statement that Chalmers Watson's birds were really suffering from "leg-weakness" is supported by this latter's remark that "the fowls showed a marked tendency to pick the lime off the walls and continued doing so for some time" and that chemical analysis of the bones "showed a great increase in the proportion of organic matter." The date at which the symptom of "leg-weakness" became marked is not specifically given but can be calculated from the context where it is stated that a tendency to lameness which had affected one of the birds was not manifest "after the fifth month" and that "a little later" the increased tendency to squat on the ground appeared. This fixes the onset of the symptoms at or about the sixth month. During the first six months the birds with the exception of one cock (No. 6), were kept in the country in a hen-run the floor of which was composed of natural soil, but at the end of six months they were transferred to iron cages in the physiological laboratory of the University of Edinburgh. The symptoms of "leg-weakness" did not therefore show themselves so long as the birds were kept in surroundings where a natural supply of grit was to be obtained. It may be further mentioned that in a later paper read before the Pathological Society in December, 1906, Chalmers Watson described effects on the bones of rats of prolonged protein feeding but in the subsequent discussion it was pointed out by Spriggs[6] that an exclusively protein diet implied a deficiency of calcium salts and of bases generally and that the osseous changes recorded were such as would result from a deficiency of these substances. Chossat[7] in 1842 showed that pigeons fed on grain freed from any accompanying grit were unduly liable to fractures and that post mortem the bones were soft. These changes did not occur if lime was added to the grain. The conclusion seems warranted that the changes in the bones described by Chalmers Watson should have been attributed not to the excess of meat but to a deficiency of lime and other bases.

DESCRIPTIONS OF ILLUSTRATIONS ON PAGE 155.

Fig 2.—Thyroid of fowl after prolonged protein feeding, showing the normal structure of the avine thyroid

Fig. 3.—Thyroid of Elenora falcon (Falco elenoræ)—a carnivorous bird—showing entire absence of vesicles and only a slight amount of colloid which is restricted to lymphatic spaces in the connective tissue trabeculæ.

Fig. 4.—Thyroid of herring gull (Larus argentatus)—a fish-eating bird—showing vesicles for the most part small and a sparse secretion of colloid. Intervesicular glandular tissue is present to considerable amount.

Fig 5.—Thyroid of ostrich (Struthio camelus)—a graminivorous bird—showing vesicles for the most part large, a free secretion of colloid, and no intervesicular glandular tissue.

Fig 6.—Thyroid of crowned crane (*Balearica pavonina*)—a graminivorous bird. Vesicles on the whole large, plentiful colloid, and little or no intervesicular glandular tissue.

Fig 7.—Thyroid of tataupa tinamou (Crypturus tataupa)—a graminivorous bird. No vesicles are present, the only colloid is that in a lymphatic beneath the capsule. The resemblance of this thyroid and that of the falcon to a parathyroid gland is marked. All the figures represent the same degree of magnification.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of The Lancet should be addressed *exclusively* "To the Editors," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of The Lancet *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index to Vol. I. of 1907, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in The Lancet of July 6th.

VOLUMES AND CASES.

Volumes for the first half of the year 1907 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of The Lancet at their Offices, 423, Strand, London, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach The Lancet Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to The Lancet Offices.

Subscribers, by sending their subscriptions direct to The Lancet Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The Colonial and Foreign Edition (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from The Lancet Offices or from Agents, are:—

For the United Kingdom.				To the Colonies and Abroad.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. Charles Good, The Lancet Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given above. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of The Lancet necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of The Lancet have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—The Manager, The Lancet Offices, 423, Strand, London, England.

2. *Hypertrophy of the thyroid glands.*—The weights of these bodies, as given by Chalmers Watson, are as follows: No. 1, no weights recorded. No. 2, no weights recorded. No. 3, weight of one thyroid, 1·25 grammes; weight of second not recorded; body weight, 1680 grammes. No. 4, weights of thyroids not recorded (stated to have been normal); body weight, 2625 grammes. No. 5, weights of thyroids, 9·5 grammes and 3·0 grammes respectively; body weight, 2540 grammes. No. 6, weight of one gland, 1·15 grammes; weight of the other gland not recorded; body weight 1640 grammes. The average weight of a thyroid gland is given as 0·14 gramme.

It will be seen that of the six fowls that were examined post mortem three showed no change in the thyroids, one showed great hypertrophy of both lobes, and in the remaining two one lobe was enlarged but no record was made of the condition of the other. This omission to record both weights in three cases and one weight in each of two cases is to be regretted, as it detracts from the value of the conclusions obtained. (*a*) Fowls vary in weight between very wide limits and an amount of thyroid tissue normal to a large bird would represent hypertrophy in a small. Nos. 4 and 6 differing so much in weight would be expected to possess thyroids differing correspondingly in weight. In my own series one bird was more than twice the weight of another, and it would obviously be fallacious to judge of the degree of hypertrophy by comparison of the absolute weights of the organs. The only trustworthy standard for comparison is the amount of thyroid gland per kilogramme body weight, and in only one of the above examples can this figure be ascertained. (*b*) The thyroid glands in birds, as in mammals, may be of unequal size,[8] and a record of the weight of one lobe alone has no value as an index to the total amount of thyroid tissue. For example, in No. 5 one gland was more than three times the weight of the other. As regards parathyroid glands my experience has been[9] that they possess no constancy of size but vary between wide limits. An examination of the thyroid glands of two full-grown healthy fowls gave the following figures:—

No.	Body weight in grammes.	Weight of thyroids.		Total weight of thyroid.	Thyroid per kilogramme body weight.	
1	1871	0·14	0·15	0·29	0·155	average 0·164
2	1899	0·15	0·18	0·33	0·174	

The following table gives the weights obtained from the four birds of my own series:—

—	Body weight in grammes.	Weight of thyroids.		Total weight of thyroid.	Thyroid per kilogramme body weight.	
Cock A.	3890	0·20	0·28	0·48	0·123	average 0·131.
Cock B.	2980	0·22	0·21	0·43	0·144	
Cock C.	2805	0·21	0·18	0·39	0·138	
Hen.	1617	0·08	0·11	0·19	0·118	

If the weights of the thyroids were considered apart from the body weight, three out of four birds would appear to have hypertrophied thyroids. The fallacy of the conclusion appears when the percentage weights are obtained. These figures show that in none of the series did the thyroid hypertrophy.

Two additional points of great importance must be borne in mind when appraising the value of Chalmers Watson's results. In the first place, enlargement of the thyroid gland is known to occur in many animals, including birds, quite apart from any question of diet. Sloan[10] has described goitre in crows and Fischer in 1896[11] stated that domestic fowls are subject to the same condition. The possibility that fowls Nos. 3, 5, and 6 were the subject of pathological goitres has not been excluded and the ascription of the hypertrophy to excessive protein eating appears premature. This is the more probable seeing that, apart from my own experiments, many other investigations on the effect of protein feeding have been conducted but, as Chalmers Watson states,[12] in none has any change in the thyroid glands been recorded.

The second point to which due attention must be given is that each of the three fowls in which the thyroid was affected presented evidence of disease elsewhere. The heart of one was hypertrophied, its duodenum was dilated, and before death its blood presented a very striking deficiency of white blood corpuscles; in the second there were very pronounced atrophic changes in the intestinal tract and the duodenum was dilated; while the third showed profound atrophic changes in the intestinal canal, a great increase of pigment in the liver, and before death a very pronounced leucopenia. If, further, it be accepted that these birds had so suffered from a want of lime and other bases as to develop in each instances "leg-weakness," and in two out of the three instances definite changes in the bones, it is obvious that it is well-nigh impossible to trace the influence of an excess of protein among so many morbid conditions, and any conclusions in this direction must be received with the greatest caution.

ON THE THYROID GLAND IN BIRDS OF PREY.

In connexion with the foregoing the comparative histology of the thyroid glands in birds is of great interest. There is a large class of birds—the raptores or birds of prey—feeding exclusively on meat and the condition of their thyroids should provide evidence bearing on the relation between the glands and meat eating. I cannot find any published records of the structure of the thyroids of these birds but I have recently, by the courtesy of Mr. F. E. Beddard, the prosector to the Zoological Society of London, had opportunities of examining post mortem representative types of the eagles, vultures, owls, falcons, and kites, as well as many non-raptorial birds. Altogether more than 30 different species were examined but no obvious difference in relative sizes between the thyroids of carnivorous, omnivorous, and graminivorous birds was noticed. Accepting for the moment the conclusions of Chalmers Watson, it would be expected that the thyroid glands of birds of prey would show to a marked degree the features he has ascribed to excessive protein feeding. It should be found (1) that the thyroids of these birds consist of large vesicles filled with colloid and that the intervesicular glandular tissue is diminished; and (2) that the thyroids of non-raptorial birds when contrasted with these show vesicles of comparatively small size, a not over-abundant secretion of colloid, and an average amount of intervesicular glandular tissue. In the specimens I have examined I find that this relation does not exist and that not only were the structural characters which we are assuming to be associated with meat-feeding not specially marked in carnivorous birds but in some instances the exact contrary was pronounced. Further, these characters were strikingly marked in many species which subsist chiefly or exclusively on vegetable food. Microphotographs of a series of avine thyroids will illustrate these points. The specimens are arranged in three groups: first, a group representing the carnivorous birds of prey; next a group of fish-eating birds; and lastly, a group of graminivorous birds.

1. *Carnivorous birds of prey.*—These are represented by the short-toed eagle (Circaetus gallicus), the barn owl (Stryx flammea), and the elenora falcon (Falco elenoræ). In the thyroid of the eagle the vesicles are of good size and contain plenty of colloid; intervesicular tissue is absent. In the owl many of the vesicles are quite small and not a few contain no colloid; intervesicular tissue is present to considerable amount. The elenora falcon possesses a striking thyroid in which no vesicles at all are present, the polyhedral cells still retaining their primitive arrangement into solid clumps; colloid secretion is present only to a very slight extent and is found occupying chiefly the lymphatic spaces in the connective tissue trabeculæ (Fig. 3).

2. *Fish-eating birds.*—The examples of these are the guillemot (Lomvia trolle) and the herring gull (Larus argentatus). In the guillemot the vesicles are not small and the sections show a lavish secretion of colloid and a minimum of intervesicular tissue. The thyroid of the herring gull contains no large vesicles anywhere and the secretion of colloid is sparse. It will be noticed that the vesicles are separated from each other by an unusually large amount of intervesicular tissue. (Fig. 4.)

3. *Graminivorous birds.*—As types of this group are the

Three Clinical Lectures
ON
GENERAL SURGICAL ANÆSTHESIA.

Delivered at the London Hospital,

BY FREDERIC W. HEWITT, M.V.O., M.A.,
M.D. CANTAB.,
EMERITUS LECTURER ON ANÆSTHETICS

LECTURE I.

Delivered on June 11th, 1907.

THE THREE MAIN PRINCIPLES OF ANÆSTHETISATION.

GENTLEMEN,—The phenomenal advance which took place in surgery during the latter half of the nineteenth century was due, as you are aware, partly to the discovery and use of anæsthetics and partly to the introduction into practice of those principles with which the name of Lister will be for ever associated. So vast and far-reaching have been the benefits which mankind has derived from these two great discoveries that any remarks upon their relative importance would be irrelevant. At the same time one may perhaps be permitted to compare the developments which have taken place in general anæsthetisation, on the one hand, with those which have occurred in antiseptic and aseptic principles on the other. The labours of workers upon the lines originally laid down by Lister have been so fruitful that, at the present time, every recently qualified medical man carries with him into practice a deeply-rooted knowledge of the doctrines of asepsis; and he is able, as the result of the training he has received in those doctrines, to apply them successfully and to see for himself what an important part they play in combating disease. But is every recently qualified practitioner equally imbued with the true principles and conversant with the best methods of anæsthetisation? Is he as fully alive to the risks of departing from those principles as he is of the risks of departing from the principles of asepsis? I fear that these questions must be answered in the negative and that there is a regrettable want of parallelism in the developments which have followed the two great discoveries in question. A close scrutiny of the best reported cases in which death has occurred during general anæsthesia convinces me that in a large number of these it was a lack of appreciation of the principles of anæsthetisation which was the important factor, and it is, therefore, with these principles that I propose to deal to-day. It is not contended, of course, that the mere recognition of abstract propositions or principles will suffice to ensure the anæsthetist against difficulties and accidents, but without such fundamental propositions or principles to guide him he will be constantly drifting into dangerous waters, from which he may find it difficult to extricate himself. Before the action of anæsthetics and the complications of general anæsthesia were fully understood patients undergoing surgical operations under a particular anæsthetic were believed to incur a risk which was definite or special for that anæsthetic, being determined by the number of persons per 1000 who, from "idiosyncrasy" or other unknown causes, were specially liable to be unfavourably affected. But such views are no longer tenable. We now know that the risks of general anæsthesia are neither in the patient nor in the anæsthetic, but in the anæsthetist; and that if the present unnecessarily high death-rate from anæsthesia is to be lessened certain reforms which I have elsewhere indicated—reforms having for their object a higher standard of efficiency in those who administer anæsthetics—must be introduced. Everyone who has had experience in this department of practice sooner or later finds himself working on certain broad lines of procedure, and it is to these broad lines that I would now direct your attention. Let me first specify what may be regarded as the three main principles under which anæsthetics should be administered and, secondly, let me illustrate the importance of these principles by giving you examples of the most common departures from them

The three main principles of general, as opposed to local anæsthetisation are: (1) the selection of appropriate anæsthetics; (2) the maintenance of unembarrassed, and particularly of unobstructed, respiration during and after the administration; and (3) the proper adjustment of the percentage or strength of the anæsthetic gas or vapour. I do not propose to weary you with any elaborate classification as to the selection of anæsthetics, the causes of intercurrent asphyxia, or the symptoms produced by this or that gas or vapour percentage. I merely wish at the present moment to draw your attention to the importance of these three main principles.

1. THE SELECTION OF APPROPRIATE ANÆSTHETICS.

One of the commonest errors in the selection of anæsthetics is the employment in cases of potential or actual respiratory difficulty of an asphyxiating agent such as pure nitrous oxide, or of an asphyxiating method such as that by which ether and ethyl chloride are respectively administered. Although nitrous oxide is the safest anæsthetic for the vast majority of subjects its use may be fraught with considerable danger in certain patients. Thus it should never be given when the air-way is encroached upon, as in angina Ludovici, in thyroid enlargement, in sublingual abscess, or in allied conditions. The safest and best anæsthetic in such cases as these is usually the C.E. mixture (two parts of chloroform to three parts of ether), and the inhaler should be one which in no way restricts the air-supply. In weakly patients and children a simple Skinner's mask will answer best. Should the patient be at all dyspnœic all methods of anæsthetisation involving rebreathing must be carefully avoided, and chloroform is generally to be preferred to other anæsthetics. In all the cases to which reference has just been made ethyl chloride is contra-indicated. Ether should not be given to emphysematous, bronchitic, or phthisical subjects.

Patients with cardiac disease pass through general anæsthesia remarkably well provided that the proper anæsthetic be chosen and that asphyxiating methods be avoided. Generally speaking, nitrous oxide and oxygen and the C.E. mixture are to be preferred to other anæsthetics. Both pure nitrous oxide and ethyl chloride should be avoided—at all events in advanced cases. It is an interesting fact that whilst nitrous oxide free from oxygen must have been administered to thousands of patients with all forms of morbus cordis singularly few fatalities have been recorded in such subjects. The most probable explanation of this circumstance is that when pure nitrous oxide is administered to a patient with advanced cardiac disease ample warning is afforded by his appearance of the approach of danger, and common sense dictates the withdrawal of the inhaler at the proper juncture. I have, however, met with a considerable amount of clinical evidence which seems to indicate that when a patient with a feeble, fatty, or dilated heart is subjected to the full effects of pure nitrous oxide the strain upon the cardiac walls at the acme of the administration may be such as to leave its mark, at all events for a time, upon the heart itself. If it be impracticable to administer oxygen with nitrous oxide, an occasional breath of air should be permitted during the inhalation of the pure gas in order to prevent any undue asphyxia.

Another common error in the selection of anæsthetics is the use of chloroform or a chloroform mixture for the operation of circumcision. In the ensuing lecture I shall place before you clinical evidence to prove that *during this* and similar operations there is a great tendency, unless the patient be deeply anæsthetised, for reflex respiratory, as opposed to reflex circulatory, disturbance to arise, and this respiratory disturbance is far more likely to prove dangerous under chloroform than under ether. Ether, in fact, is doubly indicated—first, because it can be safely and quickly pushed to that point at which reflex respiratory difficulties will not arise; and, secondly, because, if it has not been pushed to that point when the operation begins and such difficulties arise, the circulation will hold out for a much longer time than in the case of chloroform. The operation of circumcision is a short one and even in the case of infants there is practically no risk of pulmonary sequelæ following the use of ether. For infants I would recommend you to use a small Rendle's (celluloid) mask with a very small piece of sponge within it and to *sprinkle ether* from a drop-bottle in small quantities at a time upon the sponge, correcting the breath-holding (*which often disconcerts* the inexperienced anæsthetist) by frequently rubbing the lips with a handkerchief or towel. In children of from two to seven or eight years of age a few drops of chloroform or C.E. mixture may be used as the induction agent, and the from a second ovum. Chaliex[3] reports a case which appears to be very similar to the one reported above. In his case there were three male children; the first had a separate placenta, the other two had a common placenta with velamentous attachment of the cords. Westervelt[4] notes a case of uni-ovular triplets which were all females.

With reference to the influence of heredity on the tendency to produce plural births it should be mentioned that twins had occurred twice in the girl's family within recent years; two aunts, who were sisters, had each given birth to twins. Details regarding previous generations could not be obtained. Mirabeau,[5] in an analysis of 75 cases of triplets, states that they occur usually in multiparæ who have had previous abortions and who belong to families where multiple births have been observed. He also found that the mothers of triplets were generally between the ages of 30 and 34 years. Wakley[6] has clearly shown the influence of heredity on the tendency to produce plural births. The presence of triplets was not suspected until after the birth of the second child, the fœtal heart-sounds being very indistinct.

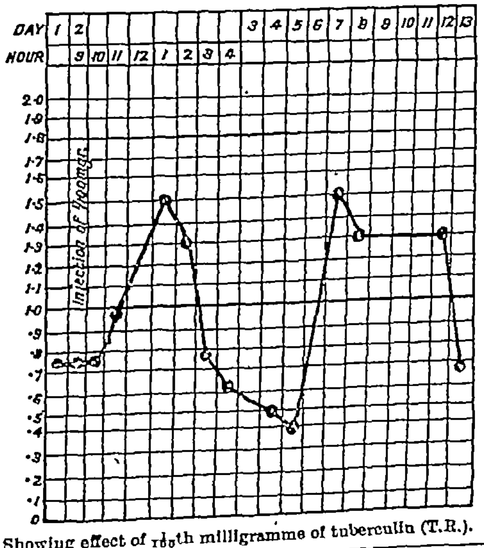
The Infirmary, Kensington, W.

ON THE EFFECT OF TUBERCULIN ON THE GENERAL TUBERCULO-OPSONIC INDEX IN TUBERCULOUS PATIENTS.

BY HENRY H. CLARKE, M.A., M.B., B.C. CANTAB.,
HONORARY PHYSICIAN TO THE LIVERPOOL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST AND PHYSICIAN IN CHARGE OF THE PATHOLOGICAL DEPARTMENT; LATE HOLT FELLOW IN PATHOLOGY, UNIVERSITY OF LIVERPOOL;
AND
HALLIDAY G. SUTHERLAND, M.B., CH.B. EDIN.,
LATE PATHOLOGIST TO THE HOSPITAL.

IT has been frequently stated that the injection of a therapeutic dose of tuberculin is invariably followed by a fall in the opsonic index lasting from three days to three weeks. This period of low opsonic index is generally known as the "negative phase" and its duration varies with the amount injected. This negative phase is followed by a period of high opsonic index, which is known as the "positive phase" and lasts for a few days, after which the index returns to about its original level. It is generally believed that by reducing the dose to the minimum that will produce any effect the negative phase may be reduced and the positive phase correspondingly increased. The doses which have been most frequently used to produce these results range from $\frac{1}{1000}$ to $\frac{1}{100}$ milligramme or even more.

CHART 1.



Showing effect of $\frac{1}{100}$th milligramme of tuberculin (T.R.).

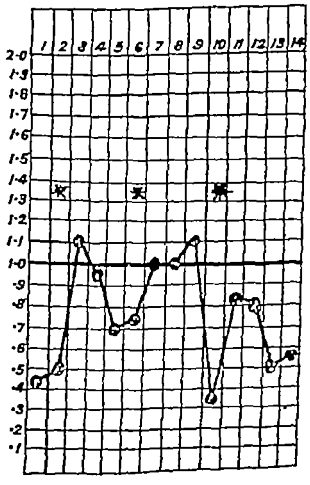
With a view to gaining more precise knowledge of the effect of a therapeutic injection we injected a phthisical patient with $\frac{1}{100}$ milligramme of Koch's new tuberculin (T.R.) and estimated the opsonic index hourly for several hours with the following result. (See Chart 1.)

1907.	Index.	1907.	Index.
Feb. 16th	0·75	Feb. 19th	0·5
" 17th, 9 A.M. (injected $\frac{1}{100}$ mgr.)...	0·75	" 20th	0·4
" 17th, 10 A.M.	0·75	" 22nd	1·5
" " 11 "	0·97	" 23rd	1·33
" " 1 P.M.	1·5	" 27th	1·39
" " 2 "	1·3	" 28th	0·76
" " 3 "	0·78	" 29th	0·8

It will be observed that a rapid rise of the opsonic index occurred within two hours of the injection; it rose to a maximum in four hours, fell to its original level in six hours, and was succeeded by the usual negative and positive phases. This initial rise may be called the pre-negative phase and has hitherto been overlooked owing to the fact that indices are rarely taken more than once a day. This pre-negative phase has since been independently observed and recorded by Dr. Olive Rivière.[1]

In order to explain these facts it is necessary to assume that when tuberculin is injected into the body the opsonins present in the blood are absorbed by the bacillary débris. Fresh opsonins are then produced and as rapidly absorbed and it is thus that the negative phase is produced. But in accordance with the law of regeneration more opsonins are produced than suffice to replace those absorbed and sooner or later a point is reached at which the tuberculin is saturated. More and more opsonins are produced until the index begins to rise and the positive phase occurs. This theory will explain the negative and positive phases but not the initial rise. To explain this phase we must assume that at the moment of injection a minute fraction of the dose found its way immediately into the circulation, probably owing to rupture of some capillaries. This minute dose absorbed sufficient opsonin to set in motion the mechanism of immunity but not enough to cause more than an exceedingly minute and transitory fall in the index. The index accordingly rose rapidly. The great bulk, however, of the injection remained at the site of inoculation until by dilatation of the capillaries and transudation of lymph it too was swept into the general circulation. This occurring some hours later the excess of opsonins produced were again absorbed and the negative phase set in.

CHART 2.



Showing effect of $\frac{1}{1000000}$th milligramme of tuberculin (T.R.), the asterisk marking the date of dose.

If this explanation be correct, then it follows that if a sufficiently small dose be given the negative phase will be absent or so slight and transitory as to be negligible and the injection will be followed by an immediate rise. We have tested the truth of this explanation in five patients on 14 different occasions by injecting a dose of tuberculin in a bulk of one-millionth of a cubic centimetre of tuberculin in a bulk of an exceedingly slight and barely audible obstruction to the entry of air—indeed, this scarcely noticeable condition has its advantages—anything more than this, particularly if it persist for some time and the patient's general condition be unsatisfactory, will be liable to be followed by undesirable effects. Symptoms of intercurrent asphyxia from faulty posture, persistent stertor or stridor, the presence of laryngeal mucus, &c., are frequently mistaken for those of surgical shock or chloroform overdosage. I could place before you a large amount of clinical evidence to prove that this auto-asphyxiation, particularly if it come about, as it usually does, in an insidious manner, may not only seriously complicate an administration, but may necessitate its postponement or abandonment. Whilst the circulation of a patient with a healthy cardio-vascular system may suffer remarkably little during a considerable degree of respiratory embarrassment, that of a feeble anæmic subject will quickly show signs of failure. It is particularly in patients of the latter class that intercurrent asphyxia should be avoided. If the operation be one which necessarily produces some respiratory embarrassment the quantity of anæsthetic administered should be correspondingly reduced.

We must *not* forget that the responsibilities of the anæsthetist do not necessarily cease with the insertion of the last suture or the application of bandages. There has been a tendency in recent years to over-anæsthetise patients, with the result that at the conclusion of operations they are often left to recover as best they may from the unnecessarily large quantities of ether with which they have been saturated. This practice has come into vogue mainly, I believe, as the result of a very laudable desire on the part of the anæsthetist to provide the surgeon with the most ideal conditions for his operations. Reflex movements, muscular rigidity, retching, coughing, &c., may doubtless be prevented by this deep narcosis, but a heavy price is sometimes paid for the benefits received in the form of pulmonary sequelæ and persistent vomiting. To saturate a patient with ether for an hour, or possibly for two hours, at a time is not without its own special risks; but these risks become considerably augmented when, as is often the case, these patients, still deeply etherised, are put back to bed upon their backs, with deep, moist breathing, insensitive corneæ, and dusky colour. If it be found impracticable towards the conclusion of the operation so to adjust the degree of anæsthesia that the patient begins to show signs of recovery immediately he is put back to bed—the ideal at which we should aim—he should certainly be carefully watched by the anæsthetist and if possible kept upon his side till signs of semi-consciousness present themselves. The airway may readily become temporarily obstructed during the recovery period, particularly if blood or mucus be present within the larynx, as after operations for adenoids. Whenever there has been any undue mucous secretion, or whenever blood or vomited fluid has entered the larynx or trachea, the patient should be placed first of all upon one side for an hour and then upon the other, so that both lungs may have a chance of expanding. I have recently met with a case in which a nurse failed to carry out these instructions and the patient, whose air passages contained some blood at the conclusion of a very long operation, was kept upon one side for 12 hours or more, with the result that the temperature rose and some crackling sounds became audible in the lung on that side. The patient was then placed on the other side with the result that she quickly coughed up some altered blood, the temperature at once fell, and the physical signs vanished. It is in the highest degree probable that had this patient been kept upon one side or upon her back a local broncho-pneumonic process would have resulted. The same principle that guides us in the administration—that of maintaining a free airway and free lung expansion—should also guide us in the management of patients during the recovery period.

3. THE PROPER ADJUSTMENT OF THE PERCENTAGE OR STRENGTH OF THE ANÆSTHETIC GAS OR VAPOUR.

Before considering the different levels of anæsthesia which are required to meet particular conditions I should like to say a few words upon what may be termed the average level of anæsthesia for surgical operations in general. In healthy and moderately healthy subjects full anæsthesia should, as a rule, be secured at the outset—i.e., the first incision should be made just as the corneal reflex is disappearing, but from this point onwards, when using chloroform or a chloroform mixture, it is advisable and generally possible to permit a very slight degree of this reflex occasionally to manifest itself. With ether, corneal insensibility may in the great majority of cases be safely maintained throughout, although an attempt should be made not to push the administration unnecessarily, for deep etherisation for prolonged periods has its own special risks afterwards. I would here submit to you an important proposition which, if not capable of application in every case of anæsthesia, is certainly capable of application in the vast majority of cases. It is that provided the respiration be freely proceeding and that the corneal reflex be present even to a slight degree the patient's general condition at the moment of observation may be regarded as satisfactory. Speaking generally, we may say that the presence of a corneal reflex indicates the existence of a sufficient degree of respiratory energy to carry on respiration and a sufficiently high blood pressure to carry on circulation. The respiratory energy will, of course, be useless if any obstruction to breathing be present, just as the vaso-motor tone will be useless if from any cause the arterial system be empty. But provided there be no obstruction to respiration and that the arterial system contain a sufficient quantity of blood, the anæsthetist need not fear any central or paralytic failure of breathing on the one hand or any circulatory failure either from the anæsthetic itself or from surgical shock on the other. If, then, whilst respiration is freely proceeding you can so adjust your administration as to retain a trace of corneal reflex you need not, in ordinary surgical cases, pay any attention to the circulation. There is a great tendency amongst those who have had but little experience to keep up unnecessarily deep anæsthesia. For example, let us imagine that we are anæsthetising a patient with chloroform and that the surgeon is half-way through a radical breast operation. Should the corneal reflex be present or should it not? The answer to this question is that it should be present, but in a slight degree; in other words, that the patient should be kept within what may be called the neutral borderland of anæsthesia, being neither too lightly nor too deeply anæsthetised. If the corneal reflex be wholly annulled for considerable periods the patient will be liable to circulatory depression *as the direct result of the operation;* hæmorrhage, though slight during the operation, will be liable to take place afterwards; the recovery of consciousness will be unnecessarily prolonged; and after-vomiting will be favoured. To sum up, we may say that by the most careful attention to symptoms the anæsthetist may, in the great majority of cases, and particularly towards the conclusion of operations, permit the patient to display a slight trace of corneal reflex.

Of the different factors which should be considered in adjusting the strength of the anæsthetic gas or vapour, one of the most important is the particular type of subject. Children, aged persons, anæmic patients, and those who have become exhausted by illness or disease naturally require weaker percentages of anæsthetic than others. I have known a patient with pernicious anæmia to display epileptiform twitchings—the characteristic signal that the administration has been pushed sufficiently far—during the third inspiration of pure nitrous oxide gas. It is a common mistake when anæsthetising comparatively feeble subjects to use a Clover's ether inhaler in much the same way as it should be used for healthy and vigorous persons. In weak and exhausted patients the re-breathing factor should either be made use of to a very slight extent or altogether proscribed, whilst the ether indicator need not be pushed beyond "2." Patients with any pre-existing respiratory derangement require very cautious anæsthetisation and dilute vapour percentages. In bad cases of empyema, for example, only the lightest anæsthesia is permissible. Similar remarks apply to patients who, from cerebral disease, uræmia, the administration of an opiate, or other causes, are in a dazed and torpid state, and also to those who are suffering from traumatic shock. But even healthy patients may unexpectedly prove to be singularly susceptible to anæsthetics and it is the duty of the anæsthetist, by carefully watching the effects produced by the agents he employs, to take the measure, so to speak, of each patient. Tall, plethoric, muscular, and particularly alcoholic subjects generally require very energetic treatment before full anæsthesia can be secured. To attempt to anæsthetise such patients in cold weather with an ether inhaler capable only of supplying a comparatively weak vapour will certainly lead to difficulties.

The next important factor in adjusting vapour percentages is the nature of the operation. Certain operations require

MULTIPLE HEREDITARY DEVELOPMENTAL ANGIOMATA (TELANGIECTASES) OF THE SKIN AND MUCOUS MEMBRANES ASSOCIATED WITH RECURRING HÆMORRHAGES.

BY F. PARKES WEBER, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE GERMAN HOSPITAL, LONDON, AND TO THE MOUNT VERNON HOSPITAL FOR CHEST DISEASES, HAMPSTEAD.

Mrs. Sarah S., of Jewish origin, is a pale, somewhat fat woman of medium height, aged 60 years. She has a number of bright red angiomata distributed over the face, ears, lips, tongue, mucous membrane of the mouth, and the conjunctival surfaces of the four eyelids. All these angiomata are small; many, including those on the tongue and inside of the mouth, are hardly as large as an ordinary brass pin's head (punctiform angiomata); the largest ones are those on the face, the biggest of which, that on the right cheek, measures five by seven millimetres in diameter. They are all of them simple capillary angiomata (telangiectases) and hardly, if at all, raised above the general surface, with the exception of some of the larger ones (on the face), which project slightly and approach either the "spider nævus" (nævus araneus) class or a kind of small superficial cavernous nævus. On the face there are likewise a few of the common hair-like telangiectases. On the mucous membrane inside both nostrils there are some telangiectases to be seen, but on the posterior wall of the pharynx and by laryngoscopic examination of the glottis I could see nothing abnormal excepting some telangiectases on the anterior surface of the epiglottis. On the fingers, and notably under the finger-nails, there are several minute (pin-point) red angiomata, which I had not observed until Professor W. Osler, when he recently saw the patient, kindly drew my attention to them. I have searched most of the rest of the body for angiomata, but have failed to find any excepting those already mentioned. She has varicose veins and slight œdema of the legs.

Both the patient's appearance and the examination of her blood (April 11th, 1907) show that she is anæmic; the red cells number 2,833,000 and the white cells 11,350 in the cubic millimetre of blood; the hæmoglobin-value (by Haldane's method) is 45 per cent. Dr. A. E. Boycott has very kindly examined blood films (of May 22nd, 1907) and reports that the red cells are pale and many of them undersized, but are not otherwise abnormal. He finds that there is no evidence whatever of myeloid reaction. His differential count of 500 white cells gives the following result: neutrophiles (polymorphonuclears), 42·0 per cent.; lymphocytes, 45·2 per cent.; intermediates, 7·2 per cent.; large hyalines, 2·4 per cent.; eosinophiles, 2·4 per cent.; and mast cells, 0·8 per cent.

I thought the coagulation time of the patient's blood was slightly increased as compared to that for an ordinary healthy person, but on using Sir A. E. Wright's coagulation tubes ("coagulometer") I found (May 28th, 1907) that the coagulation time was only about five and a half minutes, so that the coagulability is within the limits for normal individuals.

On auscultation of the heart a systolic murmur of uncertain nature can be heard. With this possible exception the thoracic and abdominal viscera appear healthy. The urine is free from sugar and albumin and normal in quantity. The brachial blood pressure by the Riva-Rocci apparatus (using the broad band) is about 135 millimetres of mercury. Dr. O. Markus by ophthalmoscopic examination of the right eye found a small central patch of chorio-retinitis.

The patient has been married twice, and by her two marriages has had nine children, eight of whom are living. shall return later to the condition of these children. The enopause occurred at the early age of 38 years. At about years of age she suffered from sore places of some kind on left leg.

he biggest of the angiomata (that on her right cheek) first observed when she was about 42 years of age. ously, to that, none had been noticed; the others, she have developed at various times since then. The eeding commenced a few years before the appearance spots on her face. During the last six years or so suffered from recurrent attacks of epistaxis, an curring on the average about every two or three t is, not including the occasions on which just a little blood can be seen on the handkerchief). During the last two years, and especially recently, the bleeding has been worse than it was before. There seems never to have been a tendency to any other abnormal hæmorrhages.

The patient's mother, who died at the age of 56 years, was certainly subject to attacks of epistaxis and had one or two "spots" on her face similar to those on the patient's. Three sons and one daughter of the patient suffer likewise from attacks of epistaxis and in two of the sons I have ascertained the presence of multiple angiomata of the skin and mucous membranes. In these members of her family, as in the patient herself, there is no history of any abnormal hæmorrhages except from the nose.

Of Mrs. S. S.'s nine children one only, Joseph L., springs from her first marriage. He is now about 42 years of age and is said to be healthy and not to suffer from epistaxis or angiomata. I have not seen him. He is married and has eight children, of whom the eldest, a girl, aged 19 years, has had epistaxis.

Lewis S., her second child (the first by her second marriage), is now about 37 years of age and looks a well-built man, not especially anæmic. He says that he has enjoyed fairly good health with the exception of occasional attacks of nose-bleeding, which first commenced when he was about eight years old. On examining him I found that there were two small "spider nævi" on his left cheek and a few scattered red punctiform angiomata on his neck and the mucous membrane of his gums, lips, and tongue. I could also make out a telangiectatic condition of the mucous membrane of the right side of the nose—that is, the side from which he says the bleeding always or generally occurs. He is married and has one child, a girl, aged 11 years, who has had epistaxis.

Albert S., the third child, is now aged 35 years. He is a strong-looking, not anæmic, man who has served as a soldier in India and has enjoyed good health with the exception of slight malaria contracted in India and the occasional attacks of nose-bleeding to which he has been subject since about the age of ten years. On examining him I found three small angiomata of the "spider nævus" class on his left cheek and several small angiomata situated on the conjunctival surface of the eyelids and the mucous membrane of the gums and lips, varying in size, but not exceeding about three millimetres in diameter. Some of the larger (doubtless older) of these angiomata are more bluish than the smaller. I likewise noted some ordinary hair-like telangiectases of the skin of both cheeks. Rhinoscopic examination showed a decidedly telangiectatic condition of the mucous membrane lining both nostrils. He is married and has one child, a boy four years old, who has not yet suffered from epistaxis.

Harriet R., the fourth child, is now aged about 33 years, and is said to enjoy good health and not to have any of the "spots" on her skin or to suffer from nose-bleeding. She is married and has one child, a girl aged nine years, who has not yet shown any tendency to epistaxis.

Jacob S., the fifth child, now about 31 years of age, is likewise said not to be subject to nose-bleeding or to have any of the "spots." I have not seen him.

Annie S., the sixth child, aged 28 years, suffered from disease (probably tuberculous) of the left knee-joint during childhood but otherwise has enjoyed fair health, though during the last three years or so she has had occasional slight attacks of epistaxis. She herself has not noticed any "spots" on her skin and on examining her face and hands and the mucous membranes of her mouth and nose I could find no angiomata.

Rachel, the seventh child, aged about 26 years, is said not to suffer from nose-bleeding or to have any of the "spots." I have not seen her.

Marcus, the eighth child, is said to have died at the age of three years from brain-trouble following a fall.

Manning S., the ninth child, aged 23 years, has been subject to occasional nose-bleeding since he was 18 years old. Otherwise he has had good health and now looks healthy. When I examined him recently I could find no telangiectases or angiomata on the skin of the face and hands or on the mucous membrane of the mouth and nose, but on the front of the chest I noted a few minute red nævi, such as very many or most persons have one or two of on various parts of their body.

Mrs. S. S. was treated for a time with arsenic and afterwards with an iron preparation which she thinks has done her good. She is frightened, she says, of having the

Ferran's failure in Spain. He practised inoculation against cholera on the same principle as the old inoculations against small-pox. The crude microbe isolated from a cholera patient was employed without fixing its strength. In Haffkine's method of inoculation against cholera there are two vaccines. The cholera microbe is first fixed at a high stage of virulence by passing through animals and is maintained at its high strength by the same process. It is necessary to mention that the cholera microbe requires air for its life and accordingly in the process of passing it through a succession of animals it is necessary to alternate this procedure with aeration of the microbe for some hours, otherwise it will die. It is in this way that the strong vaccine is obtained. But as this vaccine when injected under the skin of animals is apt to produce a slough, an attenuated microbe is used as a first vaccine. The attenuation is attained by a prolonged aeration and exposure to a continuous high temperature.

The advantage derived from using a living vaccine is that the immunity is higher and of longer duration. The disadvantage is that it has always to be prepared afresh by a bacteriologist and consequently difficulties arise in its preparation and distribution over large and numerous areas, whereas a devitalised or chemical vaccine can be preserved for a considerable time and sent out to great distances and administered by any physician who knows how to employ it aseptically.

Toussaint was the first to introduce chemical vaccines. He employed a vaccine of this kind against anthrax prepared from the heated defibrinated blood of dead animals. The method worked well as long as there were no spores in the blood. The heat to which the blood could be subjected without being coagulated—viz., 57° C.—would not destroy spores, so that if these were present and animals were inoculated the result was the death of the animals and the danger of spread of anthrax to other animals.

Many experiments were tried on similar lines by others with different kinds of microbes and on different animals, but the immunity obtained by such chemical vaccines was so short-lived that the methods could not be used for practical purposes, and so it happened that up to the time of the cholera inoculations inclusive all vaccinations were done with living vaccines.

HAFFKINE'S PLAGUE INOCULATION.

When the problem of preparing a vaccine against plague presented itself Haffkine with his experience of the cholera vaccine quickly realised the importance of endeavouring to discover a chemical preparation of practical utility. The reason for this was the distribution of the plague in numerous villages and small towns and the impossibility of obtaining a sufficiently large number of bacteriologists to prepare and use a living vaccine. With these facts in front of him Haffkine pursued several lines of research. One of these was to vary the microbial preparation and to study the effect on each of them of different processes of sterilisation. Artificial cultures of the microbe, the blood and exudation of animals dead from plague, and the pulp of their different organs were taken and subjected to heating, drying, chloroform, carbolic acid, lactic acid, or essential oils.

Inoculation with the dried powder of pulverised organs and blood of animals dead from plague was found to be by far the most effective. A few years ago Dr. Klein made a very careful investigation in this direction and was successful in preparing a powder possessing very high immunising properties. In India, however, dying animals are rapidly invaded with intestinal vibrios and bacilli and the heating and drying which were employed to devitalise the plague microbe were not sufficient to kill the spores of these extraneous microbes, so that the same difficulty met with by Toussaint recurred here in another form. Sometimes also the powder appeared sterile in culture but when injected into an animal killed it, plague bacilli being present in its blood; at other times the animal died apparently from toxins, no microbes being found. When the animal did survive it was very thoroughly vaccinated but for the reasons mentioned this method was set aside.

The most practical method of preparation was to use artificial cultures and sterilise them by heat, but it was found that the animals naturally susceptible to plague, such as rats, guinea-pigs, and monkeys, could not be vaccinated by this preparation or required many injections extending over several weeks before any immunity was established. Experiments, however, showed that an animal not naturally susceptible to plague—viz., the rabbit, which possesses a relatively high degree of resistance even to injected plague—could be rendered immune with this chemical vaccine. Influenced by this circumstance and not deterred by the other Haffkine determined to ascertain whether man could not be immunised in a similar way to the rabbit.

On *a priori* reasoning it seemed improbable but the experiment first made in the outbreak of plague in His Majesty's House of Correction at Byculla in Bombay proved the possibility of such immunisation. This epidemic only lasted a week after the inoculations but still it seemed to show that during that short time benefit had accrued from the use of the prophylactic. The result obtained at the Byculla jail was subsequently confirmed by many experiments made under varied conditions and on a larger scale, and finally, it has been established that the immunity in man is not only real and of a satisfactorily high degree but lasts for a considerable time.

These two circumstances demonstrated for the first time the practicability of immunisation by a chemical vaccine. The success of the method encouraged a trial of immunisation on similar lines against typhoid fever, and this also appears to have been attended with successful results.

Experience of the effect produced by the cholera vaccines in India from 1893 to 1896 demonstrated that immunity was obtained against attacks of cholera, but when the inoculation failed and the person inoculated was subsequently attacked the fatality was practically the same as among those not inoculated. This result pointed to antimicrobial immunity being obtained but not to antitoxic immunity, and appeared to be related to the fact that the cholera vaccine consisted of the bodies of living bacilli obtained by cultivation on solid media. Haffkine realised that the defect attaching to the cholera vaccines should, if possible, be remedied in the production of the plague prophylactic and endeavoured to prepare a material which would give, not only an immunity against attack, but also at the same time diminish fatality when an attack occurred.

In the case of microbes producing extra cellular toxins, such as diphtheria, antitoxic properties are obtained in animals by injection of the toxins. Plague cultures in fluid media do not show the presence of any appreciable toxins in the filtrate, but Haffkine observed that when he injected into animals sterilised old fluid cultures of the plague bacillus he obtained a reaction which he could not obtain to the same extent when using the microbes and the filtrate separately. This appeared to indicate that the fluid possessed properties of its own. It encouraged him to try the combination of the microbes and the fluid which later was proved to be a success. The method adopted was to use old cultures rich in bacilli and their secretions. A suitable medium for obtaining such cultures was peptone broth to which were added a few drops of butter or oil. By the end of six weeks the culture is ripe for use and its purity is ascertained by drawing off a small quantity and subjecting it to the tests already described in the first lecture. The culture is then heated at from 55° to 60° C. for 20 minutes, with the result that the microbe is devitalised. The prophylactic then becomes a chemical drug with fixed properties and can be used in measured doses like other drugs. The preliminary fixation of the biological and pathogenic properties of the microbe is under such conditions not an essential process as in the case of cholera and small-pox, where living vaccines are introduced into the system.

The dosage of the prophylactic was determined by careful observation of its effects on man, which led to the adoption of the principle gathered from the study of the results of the cholera inoculations in India. This principle consists in regulating the dose with the view of producing an average temperature of 101° F. The same dose in different individuals gives rise to different ranges of temperature. Following the above standard it is generally observed that in one-third of the inoculated the temperature may rise to 102° F. and above. This proportion should not be exceeded. The thermometer is thus used as the indicator of the reaction There is no testing of the blood in plague or cholera inocul tion for the purpose of ascertaining what dose shall given. The information obtained by the thermomete been found to be a reliable guide and supplies a very and practical method of regulating the dose. It is fact that in cholera and plague inoculations no in been observed of the inoculated groups having be only recently appeared. The occurrence in elderly persons of small multiple cavernous angiomata of the lips and mouth is probably not very rare.

The conclusions at which I arrive are the following. 1. That the disease (or morbid syndroma) which I am more especially considering in the present article affects and is transmitted by both sexes. 2. That the hæmorrhage in most cases is only from the nasal mucous membranes. 3. That in most cases the morbid syndroma is not connected with any hæmophilic tendency or any diminution of blood coagulability. 4. That the cutaneous angiomata are generally not congenital but that they are "late developmental" and usually first attract attention towards middle life. Some of the minute red spots of the capillary angioma class tend to develop into raised bluish nodules approaching the cavernous venous angioma in character. 5. That in most cases a tendency to nose-bleeding has been present from early life, or at all events many years before any cutaneous angiomata have been observed. 6. That with advancing years both the attacks of hæmorrhage and the anæmia usually become more severe. 7. That probably a kind of "vicious circle" is established, the repeated attacks of bleeding giving rise to a grave condition of anæmia, which in its turn increases the tendency to hæmorrhage. This consideration would furnish a reason for occasionally employing iron and arsenic as part of the treatment. 8. That the hereditary nature of bleeding telangiectases of the nasal mucous membrane may be compared to the occasional family tendency to suffer from hæmorrhoids, or to have ordinary varicose veins of the lower extremities, or multiple smaller varices and multiple hair-like cutaneous telangiectases on various parts of the body.[14] Hæmorrhoids in some cases may, in fact, be termed "hereditary developmental bleeding angiectases."

The study of families affected with multiple angiomata of the skin and mucous membranes might help to throw light on the general subject of pathological inheritance in man. In these cases it is the morbid tendency only which is inherited, just as it is in cases of hereditary tendency to pulmonary tuberculosis, but the study of the latter hereditary tendency is complicated and obscured by the fact that the advent of a microbe (the tubercle bacillus) is necessary for the fulfilment of the "morbid promise" or potentiality in question.

Harley-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

A CASE OF PARTIAL PERFORATION OF THE BOWEL SIMULATING APPENDICITIS; OPERATION; RECOVERY.

BY W. PERCY BLUMER, F.R.C.S. EDIN.,

HONORARY SURGEON TO THE SUNDERLAND INFIRMARY.

THE patient, a coal hewer, aged 48 years, was admitted to the Sunderland Infirmary under my care on April 21st, 1907, complaining of a very severe pain in the right inguinal region and shooting across the abdomen. The history of the case was as follows. Whilst working in the Ryhope pit about 8 P.M. on April 18th he strained himself by slipping his foot when pushing a tub. He felt as if "something had torn in his bowels." There was no acute pain felt then nor for some hours afterwards. He continued to work until midnight—the end of the shift—with only momentary interruptions. The only other symptom which caused him any trouble was an urgent desire to micturate. He was able to pass a pint of clear urine and also had an action of the bowels. After finishing his work he was conveyed home to Ryhope by ambulance car and was seen by his medical attendant very soon afterwards. On examination there was no localised tenderness in the abdomen nor did palpation or percussion reveal anything abnormal. There was dorsal decubitus with both legs drawn up and abdominal facies. The temperature was 99° F. and the pulse was 76. Twelve hours later pain began in the hypogastrium and gradually became diffused over the abdomen. Tenderness on deep pressure was present over the appendix area. The temperature was 102° and the pulse was 80. There was no sickness. The subsequent symptoms changed but little up to the evening of the 21st (the date of his admission), the temperature fluctuating between 101° and 103° and the pulse always being below 80, with a gradual diminution in tone and volume. There was no history of any previous attack.

On admission to the infirmary the patient was in a rather collapsed condition (having driven three miles) and in great pain. There were great tenderness, rigidity, and some fulness over the right iliac fossa. He had a dry tongue and a feeling of nausea but there was no vomiting. The temperature was 101° and the pulse was 104. The symptoms pointed to appendix abscess. His abdomen was opened over the appendix area within an hour of admission. Recent inflammatory adhesions were found in the neighbourhood of the appendix. A small tear through the serous coat of the anterior part of the cæcum was found situated about two inches from the root of the appendix. The inner coats were bulging through. A purse-string suture was applied to the rent and the appendix, which was healthy, was removed for safety. For the first three days after the operation the condition of the patient was one of collapse, giving rise to some anxiety, but thereafter recovery was uninterrupted, and he was discharged quite well on May 23rd.

I have not been able to find the record of a similar case. The interesting points seem to be: an apparently simple slip causing a comparatively severe injury, the man being able to work for three or four hours after the injury, and the simulation of appendix inflammation.

I am indebted to Dr. Alfred Rutter of Ryhope and to Mr. Lionel H. Booth, my house surgeon, for the notes of the case.

Sunderland.

INJURY TO SHOULDER; HERPES ZOSTER; INFLUENZA.

BY JOHN ALLAN, M.B., CH.B. EDIN.

THE following case presents several points of interest and the sequence of events is unusual. A youth, 18 years of age, was seen on March 30th, 1907, on account of injury to his left shoulder. It appeared that when at work he fell and struck the back of his left shoulder against a block of wood. On examination no bruising was seen and no fracture or dislocation could be detected. Lead and opium lotion was applied to the part. During the next day or so he complained of pain at the back of the left shoulder and arm, but nothing definite could be made out to account for it. On April 3rd there appeared a herpetic eruption on the posterior aspect of the left side of the chest and on the left arm and forearm. This was accompanied by a good deal of pain. The temperature was slightly raised and the patient felt out of sorts generally. He was put to bed and the eruption was dusted with a simple dusting powder. He was given salicylate of sodium (15 grains) thrice daily and fresh vesicles as they appeared were painted with collodion. He progressed favourably until April 8th. On that date his temperature rose to 102·6° F., he was sick and vomited frequently, and he complained of headache and sore throat. On the following day his temperature was 103·8° and a scarlatiniform rash appeared over his body. This was most marked over the lumbar region and the buttocks. The face and neck and the extremities were not affected by the rash. The throat was very much congested and he had great difficulty in swallowing even fluids. He had pains throughout the body generally, especially in the back. Five grains of quinine were given every four hours instead of the salicylate of sodium and a potassium chlorate gargle was prescribed. The temperature next morning was 103·2°, and thereafter it gradually fell to normal. The rash disappeared t and which permitted of the results being carefully tched and thoroughly checked, they possess a special lue on account of their exactness and precision.

Comparison with the Etiology of Hæmorrhoids and Ordinary Varicose Veins, Edinburgh Medical Journal, April, 1904, p. 346. In regard to the view that varicose veins are venous overgrowths, allied to venous angiomata, see A. Pearce Gould's Lettsomian Lectures in Transactions of the Medical Society of London, 1902, vol. xxv., p. 132; also W. Thorburn's remarks on Developmental Varix, Brit. Med. Jour., Nov. 17th, 1900, p. 1421; and Sir W. H. Bennett's remarks on Congenital Varix, THE LANCET, Nov. 22nd, 1902, p. 1374. For similar views regarding the etiology of hæmorrhoids see G. Reinbach, "Path.-anat. und Klinische Beiträge zur Lehre von den Hämorrhoiden," Beiträge zur Klinischen Chirurgie, Tübingen, 1897, vol. xix., p. 1; and "Hämorrhoiden im Kindesalter," Mittheilungen aus dem Grenzgebieten der Medizin und Chirurgie, Jena, 1903, vol. xii., p. 272.

The subjoined Table A shows the incidence of plague ses and plague deaths in some 18 small communities under reful control where a part of the inhabitants were inocu-ted and a part remained not inoculated; most of them are ken from the reports of Colonel W. B. Bannerman, I.M.S. he table shows their comparative liability to attack and eath and the percentage of saving in cases and deaths mong the inoculated as compared with the not inoculated.

In the Byculla jail, out of 172 not inoculated there were 12 ases of plague, six of which proved fatal, while among 147 noculated there were only two cases and no deaths—that , among the non-inoculated 7 per cent. of the population were ttacked and 3·5 per cent. of the population died, and the roportion of deaths to cases was 50 per cent., whereas mong the inoculated only 1·4 per cent. of the population were attacked and there were no deaths. The percentage of saving in cases was accordingly 80 per cent. and in deaths 100 per cent.

* Besides 32,789 in Punjab native states.

These observations refer to places where the non-inoculated part of the population had between 4·3 and 34·9 per cent. of cases and between 0·8 and 27·9 per cent. of deaths, with a proportion of deaths to cases varying between 60·1 and 96·3 per cent. The inoculated part of the population had between 0·4 and 4·8 per cent. of cases and between 0 and 2·5 per cent. of deaths, with a proportion of deaths to cases varying between 0 and 53·1 per cent. The number of cases among those inoculated was reduced by between 52·2 and 94·5 per cent. and the number of deaths by between 75·7 and 100 per cent., as compared to the incidence of attacks and deaths among the non-inoculated inhabitants of the same localities. The results observed in the inoculations made on a large scale were therefore substantially the same as those obtained in special observations made for study in restricted numbers of people living under special administrative and medical control.

Again, in Umerkhadi jail, out of 127 persons not inoculated there were ten cases with six deaths, whereas among the inoculated there were three cases and no deaths—that is, among the non-inoculated 7·9 per cent. of the population were attacked and 4·7 per cent. of the population died, with the proportion of deaths to cases of 60 per cent., whereas among the inoculated there were only 2 per cent. of the population attacked and none died. The percentage of saving in cases amounted to 74 per cent. and in deaths to 100 per cent.

The results given in these first two practically represent the results in the others; for instance, if the employees of the Southern Maratha railway be taken it will be observed that out of 760 not inoculated 35 cases occurred with 21 deaths, whereas out of 1260 inoculated 11 cases occurred with two deaths—that is, among the non-inoculated 4·6 per cent. of the population were attacked and 2·7 per cent. of the population died with the proportion of 60 per cent. of deaths to cases, whereas among the inoculated there was 0·9 per cent. of cases to the inoculated population and 0·2 per cent. of deaths with a proportion of deaths to cases of 18·2 per cent. The percentage of saving in cases amounted to 81·03 per cent. and of saving in deaths to 94·1 per cent.

Among these 18 observations there are several where the whole community was inoculated with the result that the plague was arrested. Thus in the Yerowda Jail, Poona, plague appeared and in 13 days caused three cases which were fatal. By the thirteenth day the whole of the jail consisting of 1658 persons were inoculated, one of whom was attacked, but recovered, and there were no further cases. In the Aden Prison all the prisoners were inoculated except two; these two were attacked with plague and one recovered. When inoculation was completed no cases occurred although rats were dying from plague.

Summing up these experiments as a whole, they were made in places where the *non-inoculated* people had between 1·2 and 100 per cent. of cases and between 0·6 and 66·7 per cent. of deaths, with a proportion of deaths to cases varying between 50 and 100 per cent. The *inoculated* people of the same places had between 0 and 11·3 per cent. of cases and between 0 and 4·2 per cent. of deaths, with a proportion of deaths to cases varying between 0 and 57 per cent. The number of cases among the inoculated was reduced by between 68·3 and 100 per cent. and the number of deaths among the inoculated was reduced by between 79·5 and 100 per cent., as compared to the incidence of attack and deaths among the non-inoculated people of the same places.

The conclusions derived from these observations will be more clearly followed if the comparative results are given in a graphic form and the smaller numbers excluded.

second patient was a primipara in labour for 24 hours, with a true conjugate under two and a half inches; both did well. The third patient was in her second pregnancy; the first child was delivered by craniotomy; her true conjugate was two and three-quarter inches. She was operated on near to full time; the child lived but the mother died from septic peritonitis. The fourth patient was a primipara in labour for seven hours; her true conjugate was two and three-quarter inches; both did well. The fifth patient was a primipara in labour with a true conjugate of two and three-quarter inches; both mother and child recovered. The surviving mothers all nursed their infants. Professor Kynoch discussed the question of sterilisation and considered that if the patient was intelligent enough to understand the situation, and if she was willing to undertake the risk of a second operation, then sterilisation might be omitted at the first operation. Many cases had been reported where the operation had been repeated successfully two, three, or four times on the same patient. In Frau Rittgen's case it proved fatal at the fifth repetition of the operation. In all the cases reported Professor Kynoch had sterilised the patient by ligature and division of the tubes; this he considered a trustworthy enough method and safer to the patient than hysterectomy, which should be restricted to cases of atony and suspected infection of the uterus. Some recommended waiting till labour had begun, as they thought there was less chance of hæmorrhage from uterine atony and that a dilated condition of the cervix insured free drainage of the lochia. The first fear was groundless, as the uterus contracted quite as well before as after the onset of labour. A dilated condition of the cervix was of the greatest importance. In the first two cases Professor Kynoch incised the uterus between the bars of a flat vulcanite pessary, as recommended by Cameron, to diminish hæmorrhage from the uterine incision, but in the latter cases he discarded this method and did not find any marked difference in the amount of bleeding as a result. Further hæmorrhage in the course of the operation was best controlled by grasping the broad ligaments and subsequently maintaining uterine contraction by sponge pressure. The uterine incision in all cases was a vertical one; the transverse incision of Fritsch did not seem to have proved itself in any way superior. If sterilised towels were well packed round the uterus it was not necessary to adopt Muller's suggestion of eventrating the uterus before opening into it, as this involved a very large abdominal incision. But after the uterus had been emptied of its contents and as a consequence diminished in bulk the introduction of the uterine sutures was facilitated by bringing the uterus outside the abdomen.—Dr. A. H. F. Barbour, Dr. J. M. Munro Kerr, Dr. W. Fordyce, Dr. J. Lamond Lackie, and the President made remarks on the paper, and Professor Kynoch replied.—Dr. James Lochhead read a paper on the Carbohydrate Metabolism of the Fœtus. The part played by carbohydrates in the metabolism of the fœtus was discussed with special reference to the glycogen. An attempt was made to trace the changes which carbohydrates undergo in their passage from the maternal to the fœtal organism.—Dr. Barbour, Dr. James Ritchie, Dr. B. P. Watson, Dr. M. Campbell, Dr. Fordyce, and the President discussed the subject, and Dr. Lochhead replied.—Dr. Seichu Kinoshita, professor of gynæcology and obstetrics of the Imperial University, Tokio, Japan, was elected an Honorary Fellow.

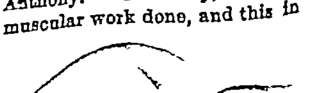
Reviews and Notices of Books.

The Nutrition of Man. By Professor RUSSEL H. CHITTENDEN of Yale University. With Illustrations. London: William Heinemann. 1907. Pp. 321. Price 14*s.* net.

THIS new work by the author of "Physiological Economy in Nutrition," which was reviewed in THE LANCET of July 8th, 1905, p. 84, covers to a considerable extent the result of the researches set forth in that work. Since the time when Professor Chittenden studied under Kühne few men have devoted themselves more assiduously to the study of the problems of nutrition in man. Indeed, in the United States this is a subject which has attracted great attention. Authors, such as Atwater and the workers for the *U.S. Bulletin*, have done an enormous amount of useful work. In the end the object is the study of human nutrition.

The present book is the outcome of a course of eight lectures which have been delivered before the Lowell Institute of Boston during the present year. The first three chapters—on Foods and their Digestion, Absorption, Assimilation, and Metabolism—do not contain anything new, but give a very readable account of these subjects. We may in passing give an example of the happy expressions from the work of Dr. Curtis on "Nature and Health" to which reference is occasionally made. "Alongside of its brother proteid gelatin stands as a prince of the blood whose escutcheon bears the 'bend' sinister. Such a one, though of royal lineage, never aspires to the throne." This has reference to the fact that gelatin cannot even go to make the very kind of tissue of which itself is a derivative. We are treated to the results of Pawlow's work in connexion with the æsthetics of eating in relation to their important influence upon the flow of digestive secretions. Perhaps the following may interest the reader—viz., that the quantity of hydrochloric acid secreted by the stomach by the normal individual under ordinary conditions of diet amounts to what would constitute a fatal dose of acid if taken at one time in concentrated form. While three distinct ways—all reflex—are admitted for the flow of gastric juice into the stomach as a prelude to gastric digestion, and although secretin is treated of in connexion with pancreatic digestion, we failed to find a reference to the part played by gastric secretion as pointed out by Edkins. The curdling of milk in the stomach causes the casein to remain for a longer period in the stomach, like any other food, and its partial digestion by gastric juice to be made certain. Hence, for these reasons milk should not be treated as a drink in our daily diet. Each animal has its own particular type of proteid adapted to its particular needs. This leads to the ingenious theory of Abderhalden that the intestinal ferments ultimately split up proteids, leaving, however, a very resistant residue, non-proteid in nature, which is termed polypeptid and which may serve as a starting point for the synthesis or construction of new proteid molecules. Cohnheim's researches, however, go to show that ferments break down proteids completely. At most, however, digestion is the handmaiden of nutrition. We come across the following remark: "How wise the provision that all sugar should pass from the alimentary canal into the portal system." We find no reference to Heidenhain's explanation. The importance of intracellular enzymes is emphasised; indeed, in all tissues and organs of the body there is present a large number of enzymes of different types, endowed with different lines of activity. Man's body is always in a state of unequilibrium; it is a sort of "maelstrom" of continuous chemical changes and decomposition at the expense of the proteids, fats, and carbohydrates of the food and tissues with the liberation of the stored-up energy of these organic compounds.

It is in the chapter on the Balance of Nutrition that the author foreshadows his views. One fact of importance is that the nitrogen outgo tends to keep pace with the income of nitrogen, the body always striving to maintain a condition of nitrogen equilibrium. The human body does not store up proteid, no matter how greatly the tissues are in need of replenishment. In man it is impossible to accomplish any large permanent storing of flesh by over-feeding and the muscular strength cannot be greatly increased by excessive intake of food. Marked permanent deposition of flesh is connected with the "regenerative energy of living cells." Race and individuality count for much. "A given diet with Cassius may lead to different results than with Anthony." Obviously, the diet must depend largely on the muscular work done, and this in



communities and they are constructed on the same principle as those relating to the smaller communities.

Diagram II. B (a copy of which we print) illustrates epidemics of different degrees of severity and the relative incidence of the disease among the not inoculated and the inoculated. The whole column represents 100 inhabitants inoculated or not inoculated, the shaded portion shows the percentage of deaths among the not inoculated, and among the inoculated. The incidence of deaths in the non-inoculated population varied between 0 8 and 27·9 per cent., whereas among the inoculated it varied between 0 and 2·5 per cent.

[*Diagram II. E* showed the saving in the number of deaths ong the inoculated compared to the non-inoculated. Each lumn represented 100 deaths which occurred among the inoculated population. The shaded portion of the column presented the number of deaths which occurred in an ual number of the inoculated population. The remaing blank portion of the column showed the percentage of aths averted by inoculation. The saving in the number of aths effected by the inoculations varied between 75·7 and 0 per cent.]

These diagrams bring out in a very clear manner the great alue of the inoculation. Stated generally, the average duction amounts to three times fewer attacks among the oculated and should the inoculated take plague the chances f death are reduced at least twice. Accordingly, the chances f escape from death are 6 to 1 in favour of the inoculated ompared to the uninoculated. In many cases they are at ast 10 to 1 in favour of the inoculated—that is, out of ,000,000 deaths among a non-inoculated population, if that opulation had been inoculated and exposed to the same fection, 900,000 lives would have been saved.

There are numerous other observations that might be noted showing the value of Haffkine's prophylactic as a rotective against plague. I shall content myself, however, y giving two further examples, one recorded by Dr. J. A. Turner, health officer of *Bombay*, and the other by Lieutenant-Colonel J. A. Cunningham, I.M.S. The first relates to the municipal employees under Dr. Turner. 7182 were inoculated and 418 were not inoculated. Out of the 7182 inoculated there were 14 attacked with plague and 13 died, being a percentage of 0·19 of attacks and 0·18 of deaths, whereas among the 418 not inoculated there were 28 attacked and 26 deaths, equal to a percentage of 6·7 attacks and 6·2 deaths. If the inoculated had suffered to the same extent as the non-inoculated they would have furnished 481 attacks with 446 deaths, instead of 14 and 13 respectively. The second refers to a small plague-stricken village in the Umballa district of the Punjab, where Lieutenant-Colonel Cunningham inoculated nearly half the population. Lieutenant-Colonel Cunningham describes the circumstances connected with the inoculations as follows:—

> The village is Chamaru, about nine miles from Umballa city, situated in Thana Ganour in the Patiala State, the population of which was 783 souls. Narain Singh, a Lambardar of the village, brought in batches to the civil hospital, Umballa, between 21st and 27th March, 1907, 312 people, comprising men, women, and children of all classes, and these were inoculated with plague prophylactic serum by Captain Ross, I.M.S., assistant plague medical officer. The Lambardar, to whom great praise is due, took this action because rats were dying of plague in the village. On the 22nd March, the day following the first batch of inoculations, cases of plague were observed amongst the people of the village, and between this date and the 14th May 64 people contracted the disease, 35 dying.
>
> We can now compare the results (which I had carefully verified on the spot by a medical officer) between the 312 inoculated people and the 471 uninoculated similarly situated in all respects, except for the difference in inoculation. Out of 312 inoculated, 13 contracted plague and four died, whilst amongst 471 uninoculated people 51 got plague and 34 died. The percentage works out for inoculated, attacks 4·15 per cent. and deaths 1 25 per cent., whereas for uninoculated the figures are: attacks 10·8 per cent. and deaths 7 2 per cent.
>
> For comparison I had the results ascertained in another village, Rampur, population 484, situated two miles from Chamaru in the Patiala State, where no inoculation had taken place. Here there were 74 attacks and 32 deaths the disease occurring simultaneously with that at Chamaru between 14th March and 14th May: the percentages here are: attacks about 15·2 per cent. and deaths 6 6 per cent. of the population. Of the four who died in Chamaru amongst the inoculated two of them showed signs of the disease the day following the inoculation, and in their case it is safe to assume that their fate was sealed by previous infection before the protective effect of the inoculation came *into* operation.
>
> It is, I think, a fair assumption that the inoculation of these 312 people saved the lives of 19 and saved 21 others from an attack of a very serious disease. If we could conceive a relative amount of immunity from death and plague throughout the Punjab, what a difference it would make in the experience of thousands of families, and in the population of the province. Even if this Umballa district, with its population of about 763,250 had been thoroughly inoculated, these figures show that about 20 000 of the 25,551 deaths from plague this season might have been averted. This and previous experience would justify the revival of an extensive inoculation campaign throughout the country.

DURATION OF IMMUNITY.

Observations in Hubli, Dharwar, and Gadag, three towns in the Southern Mahratta country where a large number of inoculations were done in 1898, tend to show that the effects lasted for several years (weekly reports of collector of Dharwar). The annual reports of the Parsee community in Bombay and the general report issued by them in 1902 seem to indicate that the effect of the inoculations lasted four or five years, though gradually it diminishes. Certain indications in a similar direction were obtained in the Punjab in observations made in 20 villages.

THE MULKOWAL ACCIDENT.

The inoculations have been going on for ten years in India, and several millions of people have undergone the operation. In these ten years there has been only one serious accident, and this was due to a departure from the technique or rules prescribed by the laboratory when opening a bottle of prophylactic in a village in the Punjab in 1902, in other words, to a faulty application of the prophylactic and not to a fault in its preparation. This accident is an important event in the history of plague operations and as the inquiry into it is of great scientific interest it is desirable briefly to record the salient facts connected with it. These facts have been gathered by a special commission of inquiry in India. Briefly, they are that the bottle was one of five filled from the same cultivation flask, and four were used without any ill effects, proving that the laboratory flask was not contaminated; further the bottle had been issued from the laboratory 26 days before being opened and when opened had no smell. This absence of smell is proof that no culture, even of a few days old, of the tetanus bacillus was present. A number of other facts confirm this conclusion. Thus the period of incubation and the duration of the disease were prolonged, which would not have been the case with an injection of a ready-made culture and toxin. It was found that the Mulkowal tetanus bacillus when experimentally introduced into a bottle of water agar prophylactic for a few days produced a very rich and extraordinarily toxic culture; 1½ cubic centimetres of this mixture of toxins and microbes would represent an infection such as never occurs in nature. The disease should therefore have been of the most fulminating character ever observed clinically; whereas, on the contrary, it was of an average character with a relatively long incubation period and duration of the disease. The syringe, moreover, with which the injections were made did not convey tetanus to those inoculated from other bottles which would have been the case if it had been infected with a rich culture of tetanus, notwithstanding a soakage for a few minutes in a carbolic solution of 1 in 20. The dregs of the bottle showed some aerobic microbes and only a poor and weak culture of tetanus such as would develop under aerobic conditions, subsequently to the emptying of the bottle. The actual contamination of the bottle was rendered possible by the local authorities having abolished the laboratory instructions of sterilisation by heat and having substituted for them momentary dipping in carbolic acid. In the opening of the bottle the cork and neck were not sterilised by passing through the flame and for withdrawing the cork soiled forceps were used which had fallen to the ground and were applied to the mouth of the bottle without sterilisation. The fact that no accident occurred while the proper technique was unaltered proves the high degree of safety with which operations on a large scale can be carried out in India.

ASSOCIATION OF SCOTTISH MEDICAL DIPLOMATES.—The annual general meeting of this association was held on June 19th at 11, Chandos-street, Cavendish-square, W. The report of the council was unanimously adopted. The retiring President, Mr. C. St. Aubyn-Farrer, was made an honorary vice-president. Dr. David Walsh was elected President for the year 1907–08, that post being tenable for one year only without break. Mr. Sydney Stephenson was re elected honorary treasurer and Dr. Arthur J. Harries was appointed honorary secretary. Mr. Skene Keith and Mr. Charles Ryall were elected to vacancies on the council. We are requested to state that Dr. Alexander Morison, Dr. O. O. Hawthorne, and Dr. T. N. Kelynack have resigned their position as members of the council of the society.

of the liquid changes or whether a deposit is produced, it is stated (p. 313) that "the organic matter in the water will be oxidised and deposited as a brownish sediment." The "brownish sediment" is not the organic matter but the manganese hydrated oxide which separates as a result of the permanganate being reduced by organic matter. In most cases the organic matter would very probably be oxidised into carbonic acid gas, water, and nitrogen, and these clearly do not form the elements of a sediment. Part III. is devoted to the important subject of food and hygiene in sickness and here again the author may be congratulated on his choice of facts and on his power of discriminating essentials from detail. On the whole, the author has carried out his responsibilities well and has succeeded where not a few fail in harmonising theory with practice so far as that is possible in the light of modern views.

LIBRARY TABLE.

Hadden's Pocket Vocabulary of Medical Terms. By HENRY PAYNE, M.D. Brux. Fourth edition. Revised and enlarged by PHILIP COWEN, M.D. Durh., and HERBERT DAVEY of the Middle Temple. London: Hadden, Best, and Co. Pp. 229. —The object of this vocabulary is to supply a want felt by registrars, Poor-law officials, and others who, not being medical men, have still much to do with the profession in the way of receiving death and other kinds of certificates. In selecting the words those have been chosen that are in most frequent use among the members of the profession; a few others are added for the help of nurses who often hear words used by a surgeon that do not indicate diseases but simply symptoms. In giving the pronunciation, the words have been divided into syllables, spelt as sounded, and those to be accented are indicated by the mark ′ placed above and beyond the syllable; in addition some of the vowels are sounded long and others short, these being indicated by the usual signs. The meanings of the words are given as simply as possible; a very short account is added of some of the symptoms of the diseases. An explanatory list of parasitic diseases is also included. The little book is a very useful one for those for whom it is intended; we can recommend it as a careful compilation.

Surgical Emergencies. By PERCY SARGENT, M.A., M.B., B.C. Cantab., F.R.C.S. Eng., Surgeon to Out-patients, St. Thomas's Hospital; Assistant Surgeon to the National Hospital for the Paralysed and Epileptic, Queen-square; and Surgeon to the Victoria Hospital for Children, Chelsea. (Oxford Medical Manuals.) London: Henry Frowde and Hodder and Stoughton. 1907. Pp. 256. Price 5*s.* net.—This is a little book likely to be useful to the junior members of the profession when confronted with surgical emergencies, or rather it should be read and the teaching contained in it should be assimilated before the emergency arises, as when sudden need occurs there is little time for referring to books. As the author mentions in the preface, it is not complete but deals with the more common of the surgical conditions in which prompt action is needed. The chapters are headed Hæmorrhage, Burns, Fractures, Strangulated Hernia, and so on. A chapter is devoted to the injuries and diseases of the ear and another to those of the eye. A dogmatic style is employed, which is best adapted for those who need help suddenly. The book is well printed in large type.

A Manual of Prescription Writing. By MATTHEW D. MANN, A.M., M.D. Revised by EDWARD COX MANN, M.D. Sixth edition, revised according to the United States Pharmacopœia of 1906. London and New York: G. P. Putnam's Sons. 1907. Pp. 232. Price 4*s.* net.—The fact that this little book has reached a sixth edition is a sufficient guarantee of its utility. The posological information is based on the United States Pharmacopœia and is prefaced by the naïve statement that "the determination of the doses for the different drugs, proper under all circumstances and conditions, is simply impossible." The remaining chapters are of equal use to English and to American students and deal with the pharmaceutical and grammatical construction of prescriptions with examples of all the various methods of exhibiting drugs, in which the metric equivalents of doses are given. A good list of incompatibles concludes the book. It is at this date somewhat strange to read in the original preface of 1878 a complaint of the lack of text-books dealing with the subject.

The Annual Charities Register and Digest. With an Introduction by C. S. LOCH, Secretary to the Council of the Charity Organisation Society. London: Longmans, Green, and Co. and Charity Organisation Society. Sixteenth edition. Pp. cccxxiv. + 705. Price 5*s.* net.—This work is undoubtedly of the utmost value and contains an enormous amount of information which is conveniently arranged and exceedingly well indexed. The index is, indeed, its most salient feature as it enables anybody who is interested in a particular case of distress to discover at once all the available methods of dealing with it. The book is prefaced by the note: "As far as possible all fraudulent institutions and societies have been excluded. It must not be concluded, however, that the entry of a charitable institution in the Register is equivalent to a general recommendation of it." Although it would be an almost intolerable task to verify the *bona fides* of every institution mentioned there is no doubt that the great majority of them are in every sense described by the word "charitable," if we except such societies as those devoted to anti-vivisection and vegetarianism, and all who take an active interest in philanthropic work will find much to interest and to assist them in this book. The excellent introduction contains a full account of the methods of Poor-law relief and the importance of its coöperation with private enterprise. A review of the year is included and short special articles are contributed on subjects such as tuberculosis, inebriates, epileptics, provident dispensaries, rescue work, and so on. The bulk of the book consists of a directory of charitable institutions for every purpose, with a summary of their constitutions.

The Manipulation and Fitting of Ophthalmic Frames. By HARRY L. TAYLOR. Birmingham: J. and H. Taylor. 1907. Pp. 117. Price 4*s.*—It is advisable that every ophthalmic surgeon should know how lenses are ground and spectacle frames made and fitted. Mr. Taylor's book gives sufficient information upon the latter subject and will repay perusal, since it does not go too technically into the question. We welcome the book as an indication that British opticians are taking more care in the fitting of glasses than has been their custom in the past. It is second only in importance to the correct ordering of lenses and should occupy their attention to the exclusion of functions which they are unqualified to deal with.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XXXV. Nos. 5 and 6. July 2nd, 1907. London: C. F. Clay. Pp. 143. Price 9*s.*—The articles contained in these numbers, which are issued under one cover, are: 1. The Innervation of the Bladder and Urethra, by T. R. Elliott, George Henry Lewes student. This is a long and carefully prepared article which does not admit of being briefly abstracted, but the chief conclusions at which Mr. Elliott has arrived from experiments upon cats, dogs, rabbits, ferrets, goats, mongooses, and other animals are that the physiological innervation of the bladder varies in different genera of animals, so that whilst in all mammals the pelvic visceral or sacral

Respiratory system.—Symptoms referable to the lungs were conspicuous by their absence, very slight bronchitis being only very rarely seen, while in no case did pneumonia or other acute inflammatory complications make their appearance. Coryza was equally rare, so much so that I failed to find a case showing this symptom from which to try to isolate the influenza bacillus. This absence of respiratory symptoms is most important in differentiating this disease from influenza, which the general distribution of the disease and its pains caused it to resemble so closely that in my preliminary account I described it provisionally as "a peculiar type of influenza-like fever." Since then I have analysed all the cases of influenza admitted to the European Hospital, Calcutta, in the epidemic year 1892 and found that throat and lung symptoms were almost riably present, while both the seasonal innce and temperature curve were entirely dis- from those of seven-day fever, which is efore certainly not influenza. The absence of iratory symptoms is, then, a very important t of differentiation of seven-day fever from enza.

irculatory system.—The heart does not appear uffer in seven-day fever in the way it so comnly does after influenza, and once the pyrexia ceased convalescence is fairly rapid. The se, however, presents a very important feature namely, a most constant and characteristic wness relatively to the temperature, just as so often seen in typhoid fever. At the very ginning it may be fairly rapid and rise to over beats per minute, but once the patient has en placed at rest in bed it rarely rises above at point. During the terminal high rise of the mperature it scarcely ever exceeds 100, being ore commonly about 80 to 90 only, while after e temperature falls finally to normal it may be or less. The great practical importance of is feature is that it nearly always allows of e difficult cases only admitted during the rminal rise of temperature being differentiated om true malaria, with which they have hitherto een almost invariably confused, for in the latter ondition when the pyrexia rises to 103° or 04° F. the pulse is nearly invariably over 100 per inute and usually up to 110 or more.

Cutaneous system.—Rashes are occasionally seen n this disease but were only noted in a small roportion even of those patients who were admitted to hospital in the early stages of the fever. In three cases out of 25 consecutive early cases a few small rose spots were detected on the abdomen, while in three more a definite rash appeared on the arms and legs, being best seen on the forearms as a mottled or measly looking eruption. A more extensive mottled appearance may also rarely occur, and such cases may be very difficult to distinguish from measles, and have, indeed, been admitted into the infectious block as cases of that disease. These rashes are very inconstant, and in this respect differ greatly from the text-book descriptions of the secondary eruption of true epidemic dengue.

THE TEMPERATURE CURVE.

I now come to the course of the fever, which can best be illustrated by the temperature charts thrown on the screen. These vary very much in accordance with the stage of the fever at which the patient comes under observation, so that it was only through careful watching of a long series of cases that I was able to recognise that the different types seen were but variations of a single disease, and so to separate it from "abortive typhoid" and "simple continued fever" so-called on the one hand, and from malaria on the other, these being the terms under which the cases have hitherto

THE LANCET.

LONDON: SATURDAY, JULY 20, 1907.

Considerations as Regards the Administrative Control of Tuberculosis.

THE recent report of the Royal Commission on Tuberculosis has raised some extremely important issues with reference to the administrative control of the disease. So great is the influence of authority in swaying public opinion that the unwarranted statement made by Professor KOCH in 1901 had practically the effect of diverting all attention from the bovine animal as a source of tuberculosis in man and of attaching, at least for the time being, an altogether distorted importance to the human bacillus. Now, after some six more years, we are face to face with a statement equally authoritative and based upon experimental data of a far more trustworthy and scientific character than the few adduced by Professor KOCH to the effect that a very material amount of human tuberculosis is undoubtedly of bovine origin—how much cannot as yet be known. The answer depends upon whether the bovine bacillus can by residence in the human economy become so altered as to be indistinguishable from the human bacillus. If this is found to be the case it is not altogether inconceivable that the bovine animal before long may be shown to be the main source of tuberculosis in man. Side by side with these revelations are others based also upon experimental research of a high order which point very strongly to the conclusion that whether from the bovine or the human source it is in infancy that the major portion of human tuberculosis is acquired and that, having been acquired, it remains latent in the glands of the body until age proclivities, puberty, overwork, overcrowding, and other forms of physical and mental strain render the body a suitable soil for the multiplication of the latent bacilli and an obvious and active tuberculosis results, accompanied by efforts on the part of the parasite to free itself from its dying host and so to perpetuate its existence. Again, certain other experiments are tending, so far as they go, to discredit the theory of infection by inhalation; this method of contracting the disease is rare, some say impossible. On the contrary, the nearest route to the lungs is said to be *viâ* the intestines—i.e., by the route by which food and other particulate matter reach the economy.

Whilst these far-reaching controversies are being waged the disease, in so far as England and Wales are concerned, continues to decrease, as evidenced by the death-rate. Indeed, the behaviour of the disease in this country seems to suggest that tuberculosis, like leprosy and typhus fever, may be tending towards extinction, and the problem in administration which is presented to all intelligent minds is as to the means by which the decrease in the death-rate may be accelerated. Is this best attempted, according to the views of the lay mind, by dealing with tuberculosis as with small-pox, by looking up all those who present even suspicions of the malady, or is it practicable to hasten the departure of the disease in a fashion which is less drastic and which will not disorganise society to such an inconvenient extent? If it be true, as the Germans say, that everyone at death manifests a focus of tuberculosis and if it be true that a very large proportion of the population would manifest some reaction to the tuberculin test, it is clear that to search out, as is the custom in outbreaks of diphtheria, all those who are carriers of the bacillus would inevitably lead to commercial and social paralysis. The bulk of the population would be segregated and the non-tuberculous would remain in an isolation of a somewhat inconvenient character. It will at once be conceded that "stamping out" methods such as these are not likely to receive the consent of Parliament; indeed, the application of such methods might materially thin the attendances at Westminster. Some regard must be had to the proportions of the problem and a first and elementary distinction has to be made between "closed" and, to other persons, harmless tuberculosis as opposed to the "open" or tubercle expectorating form of the disease. It would be well if this distinction could be appreciated and acted upon. The suggestion to impose compulsory notification of pulmonary tuberculosis upon London with its 5,000,000 people is a proposal which in our view has not been fully digested, and it is to be hoped that medical practitioners will themselves take into consideration the desirability of discussing the question from their point of view. It is one thing to notify to the health authorities cases in which their visits can obviously prove of value in the matter of cleanliness, overcrowding, instruction, and so on; it is another to label as tuberculous persons who have years of work before them and who, on the most accentuated view as regards infectivity, are of no danger to their fellows. In many cases the medical practitioner might be allowed to use his discretion as to whether he should notify or not and, if necessary, he might by some legal provision short of compulsory notification of all cases, early or late, "closed" or "open," be relieved of legal consequences in the matter of professional secrecy in this sense.

As regards sanatoriums, we have still much to learn or, perhaps, rather much to unlearn. The public has been told that with sanatoriums alone it is possible to stamp out pulmonary tuberculosis. Those who have made this statement will, we trust, live to see its confutation. Sanatoriums are useful institutions, both from the point of view of treatment and of education, but the majority of those who are entering them to-day will have solved the riddle of the universe within the next four or five years, or be a charge upon the rates or their friends. The remainder will not improbably be performing useful work and may continue to do so for many years to come. But the erection of sanatoriums upon economical lines should be encouraged, as there is no doubt that they form a useful portion of the administrative machinery necessary to deal effectually with the problem of tuberculosis. It is to be feared, however, that what may be termed the small-pox standard of infection is leading to the erection of sumptuous institutions, costing sometimes as much as £1000 per bed, and to the provision of

Table of the Duration of the Fever.

—	0-3 days.	3 days.	4 days.	5 days.	6 days.	6 or 7 days.	7 days.	8 days.	+8 days.	Total.
Typical cases	0	0	3	5	39	(76)	37	8	8	100
Terminal cases	0	4	6	10	40	(69)	29	10	8	106
Total cases	0	4	8	15	79	(145)	66	18	16	206

point of the utmost importance in separating out this disease from true epidemic dengue with three or less days' fever according to the great majority of experienced writers on that disease. As I was examining the blood of every fever case in the hospital it is impossible that I could have overlooked an appreciable number of short cases of this fever, for exceedingly few such cases without malarial parasites in their blood occurred during the months the seven-day fever was prevalent.

Convalescence.—Once the temperature is normal and the patient up and on full diet convalescence is very rapid after seven-day fever, as was pointed out by Captain J. G. Murray, I.M.S., at the recent debate in Calcutta already mentioned, this officer having had a very large experience of the disease in his wards at the European Hospital. He also stated that he had never seen a case of three or less days' duration, nor the very severe pains and joint complications of true dengue, while the pains did not return during the terminal rise of seven-day fever as in dengue. He regarded the slow pulse of seven-day fever as a characteristic point of difference from the latter disease. Another important feature of the convalescence of seven-day fever is the absence of the chronic joint pains which are often so prolonged and distressing after true dengue, producing the crippling of the patient from which the name of the affection is said to be derived, but which I have never seen in the Calcutta sporadic seven-day fever.

Relapses.—I have not yet met with a case of seven-day fever which has relapsed during the same year as the primary attack, although the same person not very rarely suffers from the disease again in a subsequent year if he remains in Calcutta, usually in a milder form with a more marked and prolonged remission of the fever, as was well illustrated by the charts of two attacks experienced and recorded by my friend Captain J. W. D. Megaw, I.M.S.,[3] in a paper in which he ably advocates the view that the seven-day fever is but a sporadic form of dengue. In the latter disease, however, even repeated relapses during a single season are very common in Indian outbreaks.

The blood changes.—The blood was examined by me in every case for malarial parasites with invariably negative results, while the protozoan parasite described by Graham of Beyrouth[4] in dengue was never seen. A differential leucocyte count was also done in over 70 cases during the first year's prevalence of the fever but with disappointing results. Without going into full details here it may be said that the total leucocytes were commonly reduced in numbers, and often markedly so, but 3000 to 4000 only being not infrequently met with, while leucocytosis was never seen. The differential leucocyte count furnished very variable results, a large mononuclear increase, quite as marked as in malaria, being by no means rare, while a lymphocyte increase with a normal proportion of large mononuclears, as in typhoid fever, was also met with, so that this test is of no value in differentiating seven-day fever from those diseases with which it is most frequently confounded.

THE CULTIVATION OF A BACILLUS FROM THE BLOOD OF SEVEN-DAY FEVER CASES.

Being struck with the resemblance between the more continued types of the seven-day fever with its slow pulse to typhoid and para-typhoid fevers I made numerous attempts to cultivate a bacillus from the vein blood, some difficulties being encountered owing to the European hospital being three miles from my laboratory, so that there was often a delay of an hour or more before the blood could be diluted with a sufficient quantity of broth. Nevertheless, an organism was obtained in pure culture in six cases during the two seasons' work, which appears to present constant features differing from those of the bacilli of typhoid and paratyphoid infections. The following are its principal characteristics. In shape and size it resembles those of the coli group and, like them, is actively motile, flagella in comparatively small numbers having been demonstrated in some of them by my assistant, Dr. G. C. Chatterjee, to whom I am indebted for much help in testing the cultural characters of the organism. It is decolourised by Gram's method of staining, grows in broth with the production of a diffuse haziness, forms a thin film on gelatin at 70° F. without liquefying the medium, and an appearance resembling that produced by the coli group on the surface of an agar tube. In a stab culture of glucose agar it does not grow very readily except in the upper part of the streak and on the surface and does not produce any gas formation. On potato it forms an invisible growth like the typhoid bacillus. In litmus milk no clotting is produced and only slight acidity results after a few days. In dextrose, lævulose, glucose, and maltose broths there is neither acid nor gas formation, but with mannite slight acid formation takes place after several days. The organism thus appears to be related to the great coli group but differs from the organisms of typhoid and paratyphoid fevers. In addition to the cases in which it was isolated from the blood a number of other cases yielded negative results so that repeated examinations are necessary in order to obtain it, but this is, perhaps, not surprising in such a mild and short fever as the seven-day one is. Clumping was obtained with the organisms when mixed with the blood of patients suffering from seven-day fever up to dilutions of 1 in 20 and 1 in 40, although not sufficiently constantly to furnish a reliable diagnostic measure, the fever apparently being too short in duration to yield much agglutinins. The presence of this organism repeatedly in the blood of seven-day fever patients points to its being probably the cause of the disease, but my observations require confirmation before this relationship can be positively asserted, while it is also desirable that similar methods should be employed in true dengue, which somewhat resembles seven-day fever.

Treatment.—Quinine is useless and tends to aggravate the headache, while I know of no drug which influences the course of the fever, although salicylate of sodium is useful in modifying the pains and belladonna is worth trying if they are unusually severe.

Mortality.—No fatal case has been met with.

Race and sex incidence.—The most striking fact in the incidence of the disease is that for the first month or two of its prevalence each year practically every patient is a sailor or someone connected with shipping on the river Hooghley. Later in the season patients are admitted from other sections of the community all over Calcutta, but it especially affects newcomers rather than those who have lived for some years in the town. For this reason comparatively few cases were seen in females, and extremely few in children, almost all the women and children admitted to this hospital belonging to the classes who are born and bred in India. Among the native classes admitted to the Medical College hospital cases are also occasionally seen, but this fever is many times rarer in the indigenous population than among Europeans, especially if the proportions of the two living in Calcutta are taken into consideration—another point in which it is at total variance with epidemic dengue.

THE SEASONAL INCIDENCE OF SEVEN-DAY FEVER COMPARED WITH THAT OF MALARIA.

The monthly incidence of seven-day fever and malaria respectively during the two years that I microscoped the blood of every case is shown in Diagram I. In 1904 the seven-day fever was prevalent from June to August, disappearing again in September, which is the month during which malarial cases rapidly increased from a prevous low level. The former remained practically absent from September, 1904, to the following April. In 1905 the seven-day fever was unusually prevalent, beginning to increase as early as May and being very numerous throughout from June to September, but rapidly declining during October and November and disappearing once more from December to the following April. Owing to a late rainy season the usual autumnal increase of the malaria did not appear until November and December, when the seven-day cases had markedly decreased. In 1906 the new fever cases were less numerous than in 1905, but they began to increase in May,

[4] Journal of the American Medical Association, 1902, p. 183.

Other races have as much right to possess a supply of healthy young men and young women as ourselves and in some instances do more than we do to secure it. The cultivation of an extreme degree of skill in athletics by those best adapted to exercise it has a tendency to reduce the numbers of the players and to relegate inferior performers to the position of spectators, and even when games are generally played their importance may to some extent be overrated. Improved physical development in the mass of young men and women of all ranks of life who have ceased to be mere boys and girls is not likely to be induced by active exertion in pursuit of a ball on one afternoon of the week when other points necessary to health are neglected. What is known as "physical culture" obtains a good deal of attention from some and the regular performance of well-selected exercises coupled with moderation in food, drink, and tobacco, plenty of fresh air, and a sufficiency of sleep will develop the body without overtaxing it, and will maintain in good health those who would find it difficult to train on the river or to indulge in cricket or in football. Exercise, however, without the excitement of personal emulation or the display of any particular skill is apparently not attractive to the young Briton. Our Volunteer battalions enlist but a small percentage of our young men, who acquire as a rule no great smartness in their drill, although, no doubt, many work hard and derive considerable benefit from it. The organised performance of gymnastic exercises by large bodies of men of the working classes such as takes place in Switzerland and in some other European countries is a form of pastime unknown to us, and we have no compulsory military training to force physical exertion upon those unwilling to undergo it. If we add the Japanese to the Swiss we shall have mentioned two nations who have not contributed to our recent athletic defeats but who might teach us much in the way of developing our national resources of physical strength without waste of time upon that which has no practical utility. We may not be willing as a nation to learn lessons from these but at any rate they may suggest the direction in which our physical training should be guided.

Let us combat "slackness," whether mental or bodily, in our children by all means, in whatever rank they may be born. There are round-shouldered loafers among the boys who cheer their school fellows at Lords as well as among those who flock in tens of thousands to witness a league football match. If it be possible to stimulate these to develop their bodies by exercises suitable to the purpose let us do so, but we need not declare them to be worse than their predecessors in order to show that they are capable of better things. Let us also not forget that the development of their minds is of equal importance with that of their bodies, if they are to become useful citizens and the fathers of a useful progeny. Let us hesitate before we avow a belief that the supremacy of our countrymen in certain games which they have sedulously practised implies national physical pre-eminence. Still less let us encourage the devotion of the young to the cultivation of physical excellence to the detriment of their future lives as individuals and as members of the community.

Population and Progress.

MR. MONTAGUE CRACKANTHORPE, K.C., a highly esteemed member of the legal profession, who is also known outside its ranks by his occasional excursions into the domain of sociology, has lately made one of these excursions with much sound of trumpet. He has republished an article on "The Morality of Married Life," which he contributed to the *Fortnightly Review* 35 years ago, has appended to it two others from the same source but of recent date, and two which have not previously appeared, and has issued the whole as a volume under the title of "Population and Progress."[1] The leading idea of the book is that it is the duty of married people to place artificial limits to increase of population; and it is a curious evidence both of the sincerity of the author's beliefs and of their fixity that his essay of 35 years ago does not appear to have been modified in any important particular prior to its republication. There are probably few persons whose minds, with regard to any important social question, could have remained stationary for so long a period, or could even now be so little influenced by the teaching of contemporary events. "Why," he inquires, "is France, where, during the last fifty years, the population has only increased by four millions, *pacific as well as prosperous*, whilst Germany, where the population during the same period had increased by twenty-six millions, is in a condition of unrest?" This was written not 35 years but only six months ago, and is curiously illustrated by the events which have since occurred in the French wine districts.

Mr. CRACKANTHORPE is apparently convinced, not only that it is the duty of married people to limit the number of their offspring, but also that, if this duty were acknowledged and fulfilled by the better classes, their example would be followed by the proletariate. He does not appear to have bestowed a thought upon the physiology of the subject, upon the methods to be employed, or upon the possible influence of these methods upon the health either of parents or of children; but he republishes a letter addressed by him to the *Fortnightly Review* in 1872, in reply to questions consequent upon the appearance of his first article. In this letter he very briefly refers inquirers to "physiological laws first enunciated about thirty years ago, and since recast with greater exactness of limitation." He mentions as authorities the treatises of RACIBORSKI (1844) and others, and adds that "M. RACIBORSKI'S latest work (1868), while properly qualifying the absoluteness of his previous conclusions, does not lessen their practical value to the bulk of the community." It would appear from this that in 1872 Mr. CRACKANTHORPE supposed that sterility could be secured by limiting sexual access to the concluding days of the intermenstrual period, but in a note appended to the present re-issue he casts doubt upon the correctness of this belief. He therein quotes, without comment, a German sentence by Dr. AUGUST FOREL, written in 1905, to the effect that conception after intercourse at the period in question, although less probable than at other times, is not excluded, and that those who trust to the supposed rule may be a gradually increasing quantity of raw meat was added to a gradually decreasing quantity of grain. For the first week the food was wholly grain, for the next two weeks three parts grain to one of meat, from the third to the fifth weeks equal parts of grain and meat, in the sixth week one part of grain to three of meat, while from the latter date (Dec. 8th, 1904) until the termination of the experiments no food except meat was allowed. By this gradual change to an abnormal diet it was hoped to avoid any initial digestive troubles, the animals being afforded an opportunity to accommodate themselves to their new food. In the earlier part of the experiments the meat given was the ordinary butcher's trimmings but later this was discarded on account of its cost and half-raw horseflesh substituted.

---

[1] Chapman and Hall, 1907.

Until the beginning of February, 1905, no alteration was observed in the birds but at this date they became listless and moping, standing about their runs without evincing any interest in their surroundings. They ceased to scratch over the gravel and two of the cocks penned with the hen lost all pugnacity towards each other and their sexual activity failed. Whereas their crowing had been frequent they now for over a month remained silent. All four birds developed diarrhœa, which soon became extreme, the droppings being watery and passed at intervals of a few minutes. Their appetites suffered no diminution and each readily ate one and a half pounds of meat a day, but as this appeared not to satisfy their hunger the amount was increased to two pounds for each bird. Simultaneously with the diarrhœa there developed an excessive thirst, the large drinking fountains having to be replenished twice or thrice a day, and the birds repeatedly buried their widely-opened beaks beneath the surface of the water, drinking greedily. No nervous symptom or joint-trouble of any sort was noticed. The acuteness of the attack lasted some two or three weeks but the droppings remained liquid till the end of the summer. By the middle of March the animals were bright and active again and their weights which had not increased during their illness began to rise. From now until their deaths they remained in the best of health except for the usual malaise associated with moulting. In November, 1905, three of them (the fourth having been recently killed) were shown at the Physiological Society and nothing in any way wrong was detected in their appearance. The hen during the two summers she was under observation laid occasional eggs. They were of normal size, the yelks were pale and the flavour excellent.

FIG 1.

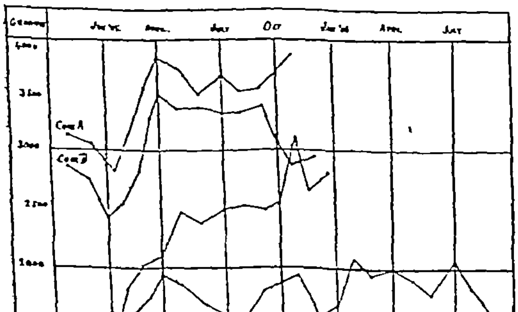

Table of weights of fowls.

A record was kept of the weights and is shown in Fig. 1. Cock A and Cock B lost weight during the first two months but thereafter rapidly increased, their progress being checked only by the acute attack described above. Cock C (a cockerel), which was at a period of rapid growth, remained constant in weight for two months and then increased until at the end of 12 months it had more than doubled its size.

POST-MORTEM EXAMINATIONS.

Each bird was killed by coal-gas and a complete post-mortem examination at once made. In each case microscopic sections were prepared of the following organs: thyroid, parathyroid, suprarenal, pituitary, spleen, liver, small intestine, kidney, pancreas, bone marrow, lymphatic gland, and testis or ovary. Specimens of these organs were fixed in 10 per cent. formalin in normal saline, prepared by the paraffin process and stained with hæmatoxylin and eosin.

Cock A (an old bird nearing the end of a period of moulting) was killed on Oct. 20th, 1905, after being on the protein diet for more than ten months. The body was very well nourished with a copious deposit of fat, especially at the root of the neck and in the abdomen. In the subcutaneous tissue covering the sternum were found numerous deposits of a chalky character, varying in size from that of a millet-seed to that of a small bean. Others occurred beneath the skin of the right thigh and one large deposit lay at the back of the neck. Their chemical examination was kindly undertaken by Dr. Foster Morley, who found them to consist of calcium phosphate with just a trace of oxalate, but no uric acid. The thyroid glands found at their normal site at the root of the neck on or near the origin of the carotid vessels were pear-shaped and somewhat translucent bodies of a pale red. The right weighed 0·20 gramme, the left 0·28 gramme. Posterior to the right and quite separate from it was a small parathyroid weighing 0·026 gramme, while in a corresponding place on the left side were two parathyroids, one anterior to the other, and together weighing 0·036 gramme. The spleen was firm and of the size of a small horse-chestnut. The bone-marrow was soft and very dark red, almost brown, in colour. The joints of the extremities were examined but no gouty deposit was present and the articular cartilages were smooth, glistening, and well lubricated by synovia. The long bones were normal in every respect (shape, density, thickness, and regularity of shaft). No gross pathological change was noted in any portion of the body.

Cock B, killed Dec. 15th, 1905, after being on the protein diet for over a year. The body was well nourished with a fairly ample deposit of fat. One or two calcareous nodules were found subcutaneously. The thyroid glands, in the usual position, were pale pinkish-white in colour and not translucent. The right weighed 0·22 gramme and the left 0·21 gramme. Close to the posterior pole of each lay a parathyroid, that on the right weighing 0·031 gramme and that on the left 0·050 gramme. The bone-marrow was dark in colour. The joints were healthy and the long bones were normal. No gross pathological change was found in any viscus.

Cock C, killed on Jan. 9th, 1906, after 13 months of meat feeding. The body was well nourished with ample deposits of fat, especially at the root of the neck. No subcutaneous calcareous bodies were present. The thyroids were pinkish-red and translucent and the weights of the right and left were 0·21 gramme and 0·18 gramme respectively. Just posterior to the left thyroid were two parathyroids weighing 0·039 gramme, while in contact with the posterior pole of the right was a bilobed parathyroid weighing 0·055 gramme. The bone-marrow was dark red—very much like blood clot. The pancreas for nearly half its length presented a curious mottled-green appearance. All the other structures, including the joints and long bones, were normal.

Hen, killed Sept. 2nd, 1906, after being on a protein diet for one year and ten months. The feathers were straggling owing to moulting. The body was very well nourished with a rich deposit of fat everywhere. A few calcareous concretions were found under the skin. The thyroid glands in the usual position appeared to be normal; they presented the customary shape, were reddish-brown, and weighed 0·08 gramme and 0·11 gramme on the right and left side respectively. Posterior to the right but not in contact with it was a small parathyroid weighing 0·018 gramme, while posterior to the left were two parathyroids, the anterior being minute and both together weighing 0·021 gramme. The bone-marrow was dark red. The joints were healthy and no change was observed in the long bones. The pituitary was pale brown. No gross pathological change was noted in any viscus.

MICROSCOPICAL EXAMINATION.

Thyroid and parathyroid glands.—The thyroids of all four birds were similar in appearance on microscopical section. The glands were divided into small compartments by delicate connective-tissue trabeculæ inclosing thyroid vesicles. These presented the usual variations in size and were lined by a single layer of flattened epithelial cells arranged round masses of colloid secretion. Intervesicular glandular tissue was almost entirely absent, as is often the case in the thyroids of birds. Occasionally the cells approached the

"Ne quid nimis."

SOME INSTANCES OF UNSCIENTIFIC ADMINISTRATION.

AN article in our contemporary *Nature* for June 13th under the above heading by Professor Ronald Ross deserves to be read widely, if it be only to inform the public what large opportunities exist in India for the successful prosecution of research into the cause, nature, and cure of diseases which yearly exact a toll of many thousands of lives; how in the Army Medical Staff there are hundreds of able men with abundant leisure and eager for employment, who having been taught in our universities and medical schools, are familiar with the use of the microscope and thoroughly competent to understand its revelations; how funds are set aside and accessible for any reasonable demand; and yet how, with opportunities, men and money forthcoming, little encouragment has been given in the past to lines of investigation which, had they been promoted and the workers encouraged, might by this time have resulted in the prevention of scourges like plague and malaria. Professor Ross's article is a scathing indictment directed against the authorities, both civil and military, for their want of support in regard to those who were found self-sacrificing enough to pursue researches on the diseases of hot climates, which differ materially from those of a temperate zone, and to emulate such work as that of Lewis and Cunningham. For such men even leave of absence was grudgingly given or altogether refused. "The officers of the Indian Medical Service had and have leisure and opportunity unparalleled. A microscope, a few test-tubes, a word from the chief, a little approbation, some evidence that scientific work leads if successful to preferment, and the authorities could have had almost for nothing scores of enthusiastic and, I will expressly add," says Professor Ross, "capital workers for the great cause of medical science. But the pigeon-holed report and the official snub awaited us and we returned disappointed to our idleness." Professor Ross dwells upon, and criticises severely, what, as an officer of the Indian Medical Service, he terms the brainless character of much of the administration. He records that he once asked his chief if he would like him to investigate fevers during his abundant leisure It will scarcely be credited that the answer given was that his "duty was *not* to investigate but to cure—as if we could do the second without the first;" and Professor Ross's experience was only that of many others. He states that not only were leave and opportunities for study reluctantly given but that the heads of the medical department were remiss in obtaining the most recent scientific literature. Sprue, ankylostomiasis, beri-beri, various forms of fever, guinea worm, and other parasites received little official attention. He makes some surprising revelations in regard to malaria. About one-third of the admissions into hospital are due to this disease and it causes a mortality, directly and indirectly, possibly of some millions a year in India, while nothing does more to hamper military, engineering, and agricultural undertakings. Its cause was discovered by Laveran in 1880, enabling an accurate diagnosis to be made promptly. But with the exception of Vandyke Carter's confirmation in 1887 literally nothing of consequence was done on the subject in India for 15 years, though the Italians and others were publishing numerous researches. Not only did these momentous advances seem to be unknown to the authorities but they were almost entirely neglected in the hospitals and not even the necessary microscopes were provided—equivalent to a failure to supply surgeons with instruments. Professor Ross was himself asked as recently as 1905 by a rich native Rajah to investigate the malaria of his domain and his expenses were guaranteed, but the presiding Civil Service genius vetoed the suggestion. He instances, in addition to his own case, that of King who many years ago prepared a good vaccine and was rewarded by being deprived of his appointment for attempting to disseminate small-pox, whilst the same fate befell Haffkine in consequence of tetanus erroneously referred to his plague prophylactic; reference to this occurrence of tetanus at Mulkowal is made by Professor W. J. R. Simpson in the Croonian lecture which is published at p. 142 of our present issue. Professor Ross refers to the ignorance of the authorities in regard to the nature and means of prevention of the spread of plague in India, when introduced into India from Hong-Kong, which has caused the death of over five millions of people since 1896.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

Sir William S. Church presided at a meeting of the distribution committee of the Metropolitan Hospital Sunday Fund which was held at the Mansion House on July 12th. The committee reported that £43,000 were available for distribution, being the smallest amount raised in recent years. For the first time since 1899, in consequence of the death of Mr. George Herring, the Fund has been deprived of an annual contribution which varied from the sum of £10,000 to £12,000, but the committee believes that the Fund is likely to benefit by a portion at least of the interest of the residue of Mr. Herring's estate. One regrettable feature of this year's collection is the considerable decrease in the offertories at some of the West-End churches. This, of course, clearly points to the growing custom among the well-to-do of spending the week-end in the country, a custom which will certainly not diminish with the increasing facilities for quick locomotion Year by year we have urged those who spend their Sundays out of London to remember the needs of the hospitals none the less and to send their contributions in their absence, but this year, at any rate, our words seem to have fallen upon deaf ears.

STREET ACCIDENTS AND FIRST AID.

THE report of the Chapter General of the Grand Priory of the Order of St. John of Jerusalem in England for the year 1906 is a document of some interest, especially that portion of it which deals with the work of the St. John Ambulance Association. The central executive committee of this department states with regard to the number of accidents which happen in the streets of our large cities from time to time that in Manchester during the year 1906 3000 cases of sudden illness or accidents occurred in the streets and received prompt aid at the hands of the police. The average number of persons requiring first aid in the streets of Manchester has exceeded 2000 a year for many years past. In the City of London the number of accidents caused by horses and vehicles numbered 1330, involving six deaths. In the City police force the possession of a St. John certificate is a *sine quâ non* for membership and the case is reported of a constable who, fracturing his shin as the result of a fall, called upon the bystanders for handkerchiefs and wood, rendered first aid to himself, and was told by the hospital surgeon who afterwards attended to him that he had probably prevented a compound fracture. Consequent on the enormous quantity of traffic in the metropolitan area the number of street accidents appears to be steadily increasing. As reported by the metropolitan police these accidents amounted in 1891 to 4766; in 1901 they reached 7995, an increase of a little over 42 per cent. in ten years. In 1903 they amounted to 10,363, an increase of over 25 per cent.

was left in the cast for four weeks. When he regained consciousness, on the twelfth day, the temperature was normal but the pulse still ranged from 100 to 110. When the cast was removed recovery was complete. He was allowed to go about with a simple collar of plaster, more for the purpose of reminding him to be careful than for anything else. A skiagram taken seven weeks after the injury showed that the second intervertebral space, where the dislocation had occurred, was a little more prominent than normal, but the vertebræ were in perfect position.

NEAT CLOTHES AND CLEAN BODIES.

THE recent honour bestowed upon one who has devoted so many years of unselfish service to those "who have none to help them" was an act of grace which all will approve but we appeal for the elimination of the word "ragged" from the official vocabulary. To speak plainly, we as a nation should be advanced beyond ragged clothes and dirty bodies, yet unfortunately this is a consummation which every thinking observer must admit we have not reached. It is true that, speaking generally, business men, clerks, shop attendants, and others of this class are well dressed and present, as a rule, a neat and attractive appearance which gains approval, but the condition of the working class is nearly always deplorable, and what a contrast does the clever artisan present with his white apron and sleeves rolled up, hard at work: he seems to be the very embodiment of labour triumphant. In the street, however, the same man appears in disreputable garments, an old hat, a seedy coat, completely reversing the spectacle of a neat and tidily clothed person as he is when engaged at his work. Surely there must be something wrong here; an ill-dressed man is depressed, an ill-dressed woman demoralised. Employers might do much to encourage their workers to leave their occupations clean and tidy and every facility should be afforded to them in the shape of bath- and dressing-rooms of doing so. Quite good clothing can be had cheaply enough and so can soap and water, and these are elements which a man should use to make himself a pleasure to himself and, need it be added, to others also.

THE DEATH OF SIR WILLIAM PERKIN, F.R.S.

THE founder of the great coal-tar colour industry has not lived long to enjoy the distinctions and honours showered upon him just a year ago, while only last month he received the honorary degree of D.C.L. at Oxford. Sir William Henry Perkin died at his residence at Sudbury, Harrow, on Sunday night, July 14th, from double pneumonia after an illness of four days. Chemical industry and pure chemistry have thus been suddenly deprived of a great leader and an earnest and successful inquirer into the nature of things. Medicine, too, will recognise that it has lost one who did eminent service in its cause, for it is abundantly evident that the discovery of coal-tar dyes has placed in the hands of the biologist and chemist a valuable adjuvant, our knowledge of the great biological processes being extended almost every day as the suitable stain reveals the nature of formation or the arrangement of structure. William Perkin's bent was unquestionably chemistry and he started the practical study of the science at a very early age. How rapidly he gained his knowledge may be seen from the fact that at the age of 17 years he was acting as a private assistant to the great Professor Hofmann in his research laboratory. The world knows now how his great discovery was made. Impressed with the importance of being able to prepare quinine artificially he attempted to make the basic substance aniline his starting-point and accordingly submitted that body to a process of oxidation. The result was the formation of an intense purple colouring matter afterwards known as aniline purple or mauve. Before he was 20 years of age Perkin, with the assistance of his father, proceeded to construct works not far from the house in which he recently died, and there to manufacture the dye on some considerable scale. Later a more remunerative process followed Perkin's discovery of a method for manufacturing alizarin (artificial madder) in bulk. He also turned his attention to artificial indigo and to the synthetic production of perfumes. In pure science his *magnum opus* was the remarkable series of papers read before the Chemical Society on magnetic rotation, the application of which has done much to elucidate the composition of compounds and their molecular weights. Perkin was born in 1838, was twice married, and leaves a family of four sons and three daughters. Two of the former are well-known chemists.

VINCENT'S ANGINA.

SINCE Vincent in 1896 described the peculiar form of ulcerative sore-throat which is now usually called after him, a number of cases of that condition have been recorded and several interesting papers have appeared. In this country the disease has been recognised and carefully worked out by Dr. H. W. Bruce[1] who describes two types—a mild diphtheroid form which is generally superficial, limited in extent and unilateral, and is not associated with swelling or injection of the fauces, and an ulcero-membranous form in which the condition spreads rapidly and is much deeper in its extent. There is a slow separation of the slough in from ten to 14 days with extensive destruction of the tonsil or uvula; in some cases glandular enlargement occurs but never goes on to suppuration. The condition may be so severe as to cause septic pneumonia and death, while, according to Mayer, endocarditis is an occasional sequela. The lesion differs from that of diphtheria, which it may resemble very closely, in that there is no formation of a false membrane as in that disease but a necrosis of the superficial layers in the part affected with the formation of an ulcer. As described by Vincent, a fusiform bacillus and a spirillum are found in this condition; the former has been regarded by Sir A. E. Wright[2] as having affinities with a trypanosome, while the latter is considered by many pathologists to be a normal inhabitant of the buccal cavity and to become pathogenic only in the presence of other micro-organisms. Dr. J. Douglas Blackwood[3] records seven cases of this condition observed in the Children's Department of the Philadelphia Hospital during the summer of 1904. Smears were made from the throats of 21 children attending the department, of which nine gave positive results. Of these nine, seven were of the superficial or mild diphtheroid type of Bruce; the other two were healthy children, in one of whom both organisms were present, in the other the bacillus fusiformis only. The actual cases of the disease began with a sudden rise of temperature, reaching 103° F. in one instance. The course of the fever was irregular and in all cases it fell by lysis. There were few constitutional symptoms, except in one case, in which the child was comatose for the first four days of the attack. The parts affected in these cases were the lips, the tongue, the gums, the cheeks, the tonsils, or the pharynx, but in none of them was there marked destruction of tissue; nor was there glandular enlargement, except that which had been present before the onset of the disease. In all of them the fusiform bacilli were present in greater numbers than the spirilla. The duration of the attack varied from four to 22 days. An interesting case of the same condition, in which the ulceration was confined to the larynx, is recorded by Dr. F.

[3] *Proceedings* of the Pathological Society of Philadelphia, vol. ix., 1906.

ostrich (Struthio camelus), the crowned crane (Balearica pavonina), the white-backed piping crow (Gymnorrhina leuconota), and the tinamou (Crypturus Tataupa). In the ostrich the vesicles vary much in size but throughout the greater part of the section they are large. There is a free secretion of colloid and intervesicular glandular tissue is practically absent. (Fig. 5.) In the crane the vesicles of the thyroid are large, the secretion of colloid is copious, and intervesicular glandular tissue is almost entirely absent. (Fig. 6.) The piping crow shows vesicles for the most part small, though here and there a large follicle appears; the amount of colloid is moderate and intervesicular tissue is present though not to a very great amount. Lastly, in the tinamou no vesicles are present, the cells of the entire gland retain their primitive arrangement, and only at rare intervals is colloid found. (Fig. 7.)

These few specimens show all varieties of structure from the thyroid with large vesicles, much colloid and little intervesicular glandular tissue, to the thyroid in which vesicles are completely absent, the whole gland consisting of tissue identical with that which constitutes intervesicular glandular tissue. Both the extreme types are represented in the carnivorous and in graminivorous birds alike and it must be concluded that the structure of the normal avine thyroid is not modified in the way suggested by any diet habits of the birds.

CONCLUSIONS.

1. Fowls kept for long periods on a protein diet but otherwise under healthy conditions show no hypertrophy or microscopic changes in the thyroid glands.
2. Their bony tissues are not affected provided the deficiency of calcium and other bases in the meat diet is made up by a supply of lime.
3. In none of the birds was any change indicative of gout observed.
4. Each of the four fowls maintained under the above conditions showed an unusual amount of colloid in their pituitary glands.
5. The thyroid glands of carnivorous birds of prey are not obviously larger, proportionately, than those of other classes of birds, nor are there any peculiarities of microscopical structure in the glands of carnivorous and graminivorous birds referable to differences in their natural foods.

(The expenses of this research were defrayed by a grant from the Royal Society to Dr. M. S. Pembrey, to whom the author is indebted.)

Harley-street, W.

MALE TRIPLETS WITH ECLAMPSIA IN A PATIENT AGED 16 YEARS.

BY ROBERT OLLERENSHAW, M.B., CH.B. VICT.

THE following case shows such a number of noteworthy points—viz., the condition of male triplets, the complication of eclampsia, and the youth of the mother and father (the age of the latter being 17 years)—that it was thought to be worthy of record.

The patient, aged 16 years, was under the care of Dr. H. P. Potter, to whom I am indebted for his kind permission to publish the case. She was admitted to the Kensington Infirmary on June 30th and was, according to her own statement, eight months advanced in pregnancy. The abdomen was slightly pendulous and rather irregularly prominent at the point corresponding to the uterine fundus. By abdominal palpation a fœtal head could be felt at the fundus and per vaginam the os uteri was found to be three-quarters of an inch in diameter; the finger-tips could define a fœtal foot through the membranes. The patient was very comfortable, the temperature being 98° F., and the pulse 90 per minute and of good quality. The urine contained 0·3 per cent. of albumin and the feet and legs were œdematous. In spite of the very considerable albuminuria the condition of the patient was such that it was decided not to bring on labour at that time and a diet of milk only was ordered. On the following day (July 1st), at 6.15 P.M., the patient suddenly became cyanosed, convulsive twitching of both arms appeared, and consciousness was lost. The cyanosis increased to an alarming extent and the pulse could not be felt at the wrist. An injection of ether (ten minims) was made into the subcutaneous tissue of the neck. It was decided that labour should be brought on at once. The patient fortunately improved, becoming semi-conscious and screaming at the slightest touch. At 7 P.M. a second convulsive attack came on and at this time the administration of chloroform was commenced, the patient becoming completely anæsthetised in four and a half minutes. The os uteri was now found to be two inches in diameter; the membranes were ruptured and traction was made on the foot which had been previously felt. Both legs were now brought down and a small male child, who appeared to be of about eight months development, was delivered. It was with difficulty made to breathe, ten minutes' artificial respiration being required. The second fœtus immediately presented by the right knee and was delivered by bringing down the legs; this child was even smaller than the first and was very cyanosed, five minutes' artificial respiration alone being sufficient to cause spontaneous breathing. The third child was larger than either of the two previous; it presented by the brow and forceps were applied for its delivery. The patient improved considerably under the anæsthetic, the pulse at the end of the labour being much better than at the commencement; a hypodermic injection of strychnine was given during the anæsthesia. The third fœtus was contained in separate membranes and was the result of fertilisation of one ovum; the first and second fœtuses were uni-ovular, having a common chorion, the individual amniotic sacs having been broken through probably by fœtal movement. The two placentæ were united by their edges so as to form one large placenta, which was expelled quite intact with the membranes five minutes after the birth of the third child. The uterus contracted well after a hypodermic injection of ergotin (grain 1). The children were all males and their respective weights were as follows: the first, 2 lb. 14 oz.; the second, 2 lb. 6 oz.; and the third, 3 lb. 2 oz. In connexion with these weights it is interesting to note that the third, and heaviest, child was nourished from a separate placenta, and of the first two children, who shared one placenta between them, the cord of the smaller child was attached at the extreme edge of the placenta.

Porak[1] states that the weights of twins are rarely alike and that the point of attachment of the placenta appears to have much influence upon the nutrition of the fœtus. In the case above reported, however, the placental attachment was entirely at the uterine fundus; the chief factor controlling the fœtal circulation and consequently fœtal development seems to have been the points at which the cords were inserted into the placenta.

The mother's state was critical for the 12 hours following delivery, the pulse-rate varying from 136 to 150 per minute and the quality leaving much to be desired. At 10.45 P.M. (three hours after delivery) the patient became very restless and threw herself from side to side, flinging her arms about, and would have thrown herself to the floor had she not been restrained; she was in a dazed condition and screamed when held. This state of affairs lasted for four or five minutes, at the end of which time she became quiet and somewhat exhausted. Hot-water bottles were applied and the foot of the bed was raised two feet from the floor. The condition improved and a fairly good night was passed, with no return of convulsions. The albuminuria, which before delivery was three grammes per litre, fell gradually, and on the following day (July 2nd) was 1·5 grammes per litre; on July 3rd it was one gramme per litre and crystals of uric acid were deposited in the urine. On this occasion only was uric acid found. The percentage of albumin decreased quite steadily. On June 30th there were three grammes per litre; on July 1st, two grammes; on the 2nd, 1·5 grammes; on the 3rd, one gramme; on the 4th, 0·75 gramme; and on the 5th, 0·5 gramme. The excretion of urea during the period covered by the above figures was always subnormal but not to any great extent, ranging as it did from 1·3 to 1·6 per cent. On July 2nd there was evidence of bronchitis, probably due to the prolonged chloroform administration; pain in the chest was also complained of. A jacket poultice was applied every four hours and relief, accompanied by disappearance of the bronchitic signs, followed in 24 hours.

With regard to the fact that all the children were of the male sex Dr. H. F. Lewis[2] states that uni-ovular triplets are always of the same sex. In this case, however, the first two children only were uni-ovular, the third being developed by a fistula or, more usually, to the passage of fæcal matter containing microbes which cause intravesical putrefaction and formation of gas. The other and more important form is due to fermentation of the urine. This form may be divided into two varieties, diabetic and non-diabetic. In the former glucose is fermented by yeast or, more usually, the colon bacillus with the production of carbon dioxide. In the non-diabetic variety the albuminous urine of cystitis is fermented with production of carbon monoxide and hydrogen. It is this form which is of chief clinical and bacteriological interest to-day. Only eight cases have been satisfactorily investigated from the bacteriological standpoint. In three cases the organism was the bacillus lactis aerogenes, a microbe closely resembling the bacilli of the colon group but characterised by the production of slime, capsule formation, and production of gas on all ordinary culture media. Four cases were due to the colon bacillus or a closely related organism. The organism present in Dr. Taussig's case belonged to the group of colon bacilli, but it resembled the bacillus lactis aerogenes in that the first few generations on artificial media produced gas. Some bacteriologists hold that this organism is closely related to the colon bacillus. The albuminuria of ordinary cystitis and the ordinary colon bacillus do not appear to be sufficient for the production of pneumaturia. Otherwise the condition would be much more frequent than it is. The urine must contain some unusual albuminous constituent or some special strain of colon bacillus. In most of the cases of pneumaturia there was some interference with micturition. Treatment must be directed against the underlying diabetes or cystitis.

THE TENURE OF OFFICE OF MEDICAL OFFICERS OF HEALTH.

WE drew attention a few weeks ago to the urgent necessity for placing medical officers of health in the provinces upon the same terms as regards their appointments as their metropolitan and Scottish colleagues. We suggested to the President of the Local Government Board that he should at any rate make the appointments non-lapsing of medical officers of health of combined districts who devote their whole time to their duties. We have soon been provided with an illustration of the way in which a district council may take advantage of the present system of short term appointments and perpetrate an injustice not only to an individual medical officer of health but to the public health service generally. Mr. Charles Wills has been for 28 years medical officer of health to several districts in Nottinghamshire. He has been re-elected by each sanitary authority for periods of one year and when his re-election was recently considered by the Southwell rural district council a motion was carried by a majority of two that his salary should be reduced from £214 per annum to £107. The only apparent reason for this extraordinary action of the council appears to be that the Local Government Board, after perusing Mr. Wills's annual reports, has recommended the appointment of an additional sanitary inspector. This new appointment costs the district £100 a year and it appears quite just to the majority of the members of the district council that Mr. Wills should be made to pay for doing precisely what he is required to do by the Orders of the Local Government Board—namely, to report upon the sanitary circumstances of the district. It is difficult to believe that the central authority will sanction the proposal of the Southwell council. The salary which Mr. Wills has hitherto been receiving is by no means exorbitant considering the size of the district, 177,484 acres and its population of 19,000 persons. The members of the council appear to have very little idea of what would be adequate remuneration for the work which has to be done by the medical officer of health, for at the last meeting of the council one gentleman made the extraordinary statement that £214 was a fair figure for a medical man to give his whole time in one district. If this view is held to any great extent by members of other sanitary authorities throughout the country it is not surprising that rural district councils should have received such sweeping condemnation as that to be found in the report of Sir John Dickson-Poynder's select committee upon the housing of the working classes.

ROYAL SOCIETY OF MEDICINE.

WE are informed that proposal forms for candidates for election either as Fellows or as Members of one or more of the society's sections are now ready and can be obtained upon application to the secretary, 20, Hanover-square, London, W. The library of the Royal Society of Medicine will be closed on Thursday, August 1st, and will probably remain closed until the end of September in order to allow time for the considerable alterations that will have to be made in view of the increased use of the library which is anticipated.

THE INCOME TAX REDUCTION LEAGUE.

WE have received a circular letter from the general committee of the recently formed Income Tax Reduction League with a request to give publicity to its purposes. Since the medical profession as a body feel the burden of the tax especially heavily, we have pleasure in stating the objects of this league and we wish it success in their attainment. The committee's letter states that:

> The Income Tax Reduction League has been formed because we feel that the time has arrived when this tax should no longer be maintained at a war rate. The income tax is essentially an emergency tax and we consider the prolonged maintenance of the tax at a war rate to be unsafe from a national point of view, unwise from the revenue point of view, injurious to our trade and industries, and unjust to a large body of the citizens of this country.
>
> The league is a non-party body. Its objects are to unite the forces of income tax payers of all parties and of either sex in one strong association whose efforts to effect reform in the income tax will not lightly be ignored by any Government. The specific purposes of the league are: (1) to organise income tax payers for purposes of self defence; (2) to impress upon our countrymen the necessity for a substantial reduction of the rate; and (3) the restriction of income tax to profits actually received by shareholders or by individual traders and to exempt depreciation funds from the operation of the tax.

Subscriptions are invited from sympathisers, which will be received by the honorary treasurer of the league, care of Messrs. Robarts, Lubbock, and Co., Lombard-street, London, E.C., or by the honorary secretary, 2, Cloisters, Temple, London, E.C. The president is Lord Avebury and Mr. Hallett Fry is acting honorary secretary and treasurer.

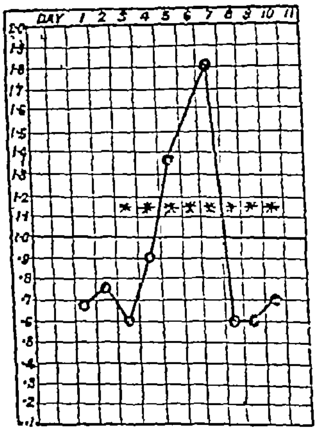
THE TREATMENT OF SUPPURATIVE PYELITIS BY LAVAGE OF THE RENAL PELVIS.

WHEN a purulent pyelitis does not yield to internal medication, if such a happy result ever follows medicinal treatment, there are only two courses open to the surgeon: he may either open the renal pelvis by an incision in the loin and then treat it by local applications, or he may wash out the pelvis of the kidney by means of a ureteral catheter. When possible the latter is the better method, but ureteral catheterisation is by no means easy. Kelly in 1894 was the first to show that it was possible to wash out the renal pelvis by a catheter passed into the ureter, but all his work was done in women, and catheterisation in the male is much less simple. Dr. Winfield Ayres of New York has obtained the best results by employing a direct-view catheterising cystoscope, which he devised, and in the May number of the *International Journal of Surgery* he describes six cases in which he has used this method. The results varied with the condition present; when no real kidney substance was left only slight improvement occurred, but when the suppurative process had only affected the kidney itself to a small extent rapid improvement or recovery followed. In most of the cases the gonococcus was present

1·7 minims. (See Chart 2.) On every occasion the injection was followed by an immediate positive phase lasting from two to four days, after which the index resumed nearly its former level and the negative phase was absent. In one case, that of a child aged ten years, the positive phase continued to the sixth day.

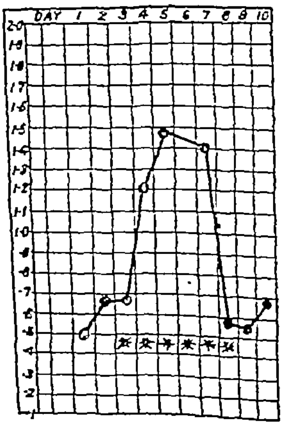
The next question which arose was whether by repeated injections one positive phase could be superimposed upon another, and if so how far could the process be carried. With this object a dose of one-millionth of a cubic centimetre of tuberculin was injected into two patients on six successive days with the following results. (See Charts 3 and 4.)

CHART 3.



Showing effect of eight successive daily injections on dates indicated by asterisks of $\frac{1}{100000}$th milligramme of tuberculin (T.R.).

CHART 4.



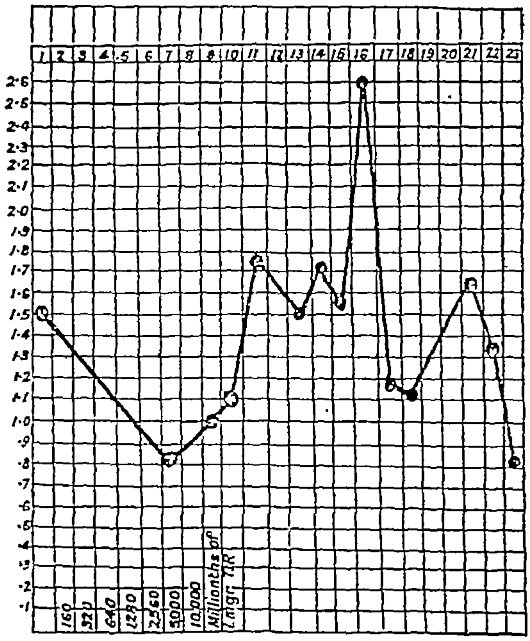
Showing effect of six successive daily injections on dates indicated by asterisks of $\frac{1}{100000}$th milligramme of tuberculin (T.R.)

	Case A.		Case B.	
	Dose.	Index.	Dose.	Index.
1st day	0	0·66	0	0·75
2nd ,,	1	0·65	1	0·5
3rd ,,	1	1·2	1	0·9
4th ,,	1	1·49	1	1·37
5th ,,	1	—	1	—
6th ,,	1	1·4	1	1·8
7th ,,	1	0·59	1	0·6
8th ,,	0	0·56	1	0·6
9th ,,	0	0·68	1	0·7

It will be seen that the first three doses were followed by successive rises in Case A and the first four in Case B. In both cases the fifth injection was followed by a rapid fall to below the original level. Here the rise was higher and more prolonged than any previously produced in the same patients by a single injection and it seems reasonable to assume that this was due to a superimposition of positive phases. It is, however, obvious that this piling up of positive phases is only possible within very narrow limits. The mechanism of immunisation is one of delicate adjustment and is easily deranged. Apparently a very slight excess of tuberculin suffices to turn the scale and convert an over-production of opsonins into a deficit.

We have repeatedly tried the effect of injecting tuberculin according to the method suggested by Weber's law. This method has for its foundation the fact that in some classes of phenomena in order to produce effects increasing in arithmetical progression it is necessary to use stimuli increasing in geometrical progression. This method appeared to be successful in certain cases but the results are inconclusive. As an instance of the result produced by these means the following observations may be taken. (See Chart 5.)

CHART 5.



Effect of a series of rapidly increasing doses.

	Index.	Dose (millionths of 1 mgr. T.R.).		Index.	Dose (millionths of 1 mgr. T.R.).

From this table it would appear that it is possible by rapidly increasing doses to raise the *opsonic index* for a considerable period. We are not, however, at present justified in stating this as a fact universally true.

We have had under observation 32 tuberculous patients during the last six months. We have estimated the opsonic index on 492 separate occasions. In the present communication we do not pretend to define the value of tuberculin in treatment, or of the opsonic index as a guide to that treatment. It has first to be discovered how the opsonic index can be artificially modified, and only later does the problem arise as to what the effect of that modification is on the patient's health. We here have only ventured t record a few of our observations in the hope that they m be of some slight assistance to other workers in the sa field.

by arranging for special investigations and reports to be prepared in elucidation of some important matters which would come under discussion. The Foreign Office had already forwarded special invitations to foreign Governments and a considerable number of delegates had signified their intention of attending the Congress. In addition to the accommodation which the University of London was providing for the Congress he (Mr. McKenna) was also placing certain rooms at South Kensington at its disposal. Sir Lauder Brunton has not a high opinion of the practical sympathy of the Board of Education, which he describes in a letter to the *Times* as being limited to a small donation in money—this being in direct controversion of the statements of the Minister of Education. We hope that Sir Lauder Brunton is wrong in his estimate of the capacities both for work and sympathy of the Board of Education.

THE Department of Public Health of Queensland in a bulletin dated June 1st states that for the week ending on that date there were 3 new cases of plague notified after an interval of 43 clear days since the last case notified on May 27th. The three cases were as follows: Case 31, a schoolboy, aged 12 years, notified only after death; Case 32, a male, aged 16 years, attacked on May 24th; and Case 33, a male, aged 17 years, attacked on May 27th. The two latter cases were both employed in a hotel. Another case, that of a girl, aged 12 years, was reported from Ipswich, near Brisbane, on May 23rd. Port Douglas is now considered as free from plague. As regards the Cape Colony, the medical officer of health of the colony states that for the week ended June 22nd 1 case, that of a European female, was discovered at King William's Town. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on July 12th states that for the week ending July 10th there occurred 1 case of plague and 1 death from the disease.

Looking Back.

FROM

THE LANCET, *SATURDAY*, July 18th, 1829.

THE PHARMACIE CENTRALE OF PARIS.

THE *Pharmacie Centrale* is no doubt one of the "most beneficial institutions under the superintendence of the Administration Generale." Its object is to supply all civil hospitals, lunatic asylums, prisons, poor-houses, and public charitable institutions of every description in Paris, as well as in the departments, with drugs and medicinal preparations. It is obvious that this manner of proceeding is both simple and economical, and best prevents all adulterations and impositions with respect to the preparing and selling of medicines. Every month the Parisian hospitals send a report to the Pharmacie Centrale of their present supply; the provincial institutions send their reports every other month. The receipts which are transmitted by the different institutions to the "Pharmacie Centrale," serve to check its annual accounts with the Administration Generale. In the year 1822, the amount of its whole expenses was not more than 423,222 francs, which, considering the extent of its operations, will appear very trifling. The institution possesses a large building, with the necessary warehouses, laboratories, &c., and an excellent apothecary's shop, which serves only as a model, no medicines being sold there.

The "Boulangerie" and "Cave Generale," are institutions similar to the Pharmacie Centrale; the latter fort [illegible]pply of wine, the expense of which in 1822, amounted to 573,532 francs. The "Boulangerie" requires annually 15,000 sacks of meal. During the last 15 years, the amount of its supply was 15,500,000 francs. In 1822, 2,820,064 lbs. of white bread and 4,223,030 lbs. of rye bread were consumed.

REPORT OF AN INQUIRY AS TO THE EXISTING SUPPLY AND THE PRESENT RATE OF REMUNERATION OF MIDWIVES IN ENGLAND AND WALES.

THE Association for Promoting the Training and Supply of Midwives appointed an advisory committee last year (1906) to consider the whole question of the supply of midwives (especially in view of that part of the Midwives Act that will come into operation in 1910) and to collect the necessary information. The latter function was intrusted to a subcommittee, consisting of Mrs. Wallace Bruce, Dr. C. J. Cullingworth, Mr. A. G. R. Foulerton, Miss Gill, Miss Alice Gregory, Mr. T. Almond Hind (chairman),[1] Miss Lucy Robinson, Dr. E. C. Seaton, and Miss Wilson, with Mrs. E. V. Lucas as honorary secretary. The instruction to this subcommittee was to inquire in the first instance as to what evidence there is of a need for an increased supply of midwives —i.e., for a supply beyond such as is likely to be afforded by voluntary charitable effort and by private enterprise on the part of the trained midwives themselves. The subcommittee was asked to formulate its answer by tabulating the existing information as to (*a*) the number of midwives retiring; (*b*) the number or proportion of untrained midwives on the roll—i.e., of women admitted to the roll within the first two years after the passing of the Act, in virtue of their having been in *bonâ-fide* practice as midwives for the 12 months preceding the passing of the Act; (*c*) the average rate of payment of midwives in private practice, especially in rural districts, and the average number of cases which they attend annually; (*d*) the proportion of rural districts in which it would, and the proportion in which it would not, be possible for a midwife (under existing restrictions as to her following other occupations)[2] to earn a livelihood; and (*e*) the extent to which it may reasonably be expected that the need would be met by existing voluntary organisations. The subcommittee was also asked to obtain further information on these various points where the existing information is inadequate.

It will be seen that the inquiry upon which the subcommittee was asked to enter was of very wide scope and it will easily be understood that the task of collecting and arranging the desired information has been a formidable one. By a careful division of labour, however, a considerable amount of very valuable information has now been collected and (thanks especially to the kindness of Mr. Foulerton who most generously placed his large experience in the compilation of statistical reports at the subcommittee's disposal) has been arranged in tabulated form. The following is a summary of the results of the inquiry as embodied in a report presented to the advisory committee on June 14th, 1907.

(*a*) *Number of midwives retiring.*—On the passing of the Midwives Act of 1902, and especially on the publication of the rules of the Central Midwives Board, large numbers of women in every county of England and Wales signified their intention to retire from practice. Thus, for example, up to the month of October, 1904, out of 106 practising midwives in Cambridgeshire 88 expressed their intention of ceasing to practise, as did 541 out of 582 in Cheshire, 377 out of 417 in the county of Durham, 419 out of 481 in Gloucestershire, 479 out of 553 in Worcestershire, and 725 out of 800 in the West Riding of Yorkshire. Many of those giving up practice were no doubt "undesirables," either on account of their age or of their incompetence; but in some districts this wholesale retirement has left extensive areas of country entirely without midwives and in that way, for the present at least, has occasioned a considerable amount of hardship. It may be mentioned here that the total number of midwives on the roll up to the end of 1906 was 23,278, of whom it is estimated that only about 14,430 are practising midwives, the majority of the remainder being engaged in monthly nursing, &c.

The number of known deaths amongst midwives on the roll during the years 1904–06 was 194; this number is manifestly far below the truth. The deaths must of necessity, hæmorrhages from her nose altogether stopped, but although her blood coagulability is not abnormally low I am trying treatment with calcium lactate, having heard from Professor Osler of a good result apparently obtained by this method in one case. Calcium lactate (in daily doses of 15 grains) has now (July 13th) been taken for some weeks, but as yet apparently without any benefit. The patient has likewise been given a very dilute adrenalin solution to apply locally with a camel's hair brush whenever the epistaxis commences. This also has in the patient's hands apparently failed to arrest the hæmorrhage.

---

[1] To the great regret of the subcommittee Mr. Hind was unable to attend its meetings or to take any part in its proceedings. In his absence Dr. Cullingworth was appointed to act as chairman.

[2] Rule 15, Section E, of the Rules and Regulations of the Central Midwives Board reads as follows: "No midwife shall undertake the duty of laying out the dead, or follow any occupation that is in its nature liable to be a source of infection."

Remarks on the literature of the subject.—The first account of this malady in which several family groups of sufferers are referred to is that published in 1901 by Professor Osler entitled "A Family Form of Recurring Epistaxis associated with Multiple Telangiectases of the Skin and Mucous Membranes."[1] In it he has included three cases of his own. Recently Dr. Brown Kelly has reviewed the whole subject in his paper on Multiple Telangiectases of the Skin and Mucous Membranes of the Nose and Mouth,[2] which is accompanied by excellent coloured illustrations. I have arranged the following data from the published accounts under the various cases or families.

Family 1.—B. G. Babington[3] in 1865 published notes of a family showing a most remarkable tendency to epistaxis, but he makes no mention of the presence of angiomata or telangiectases of the skin or mucous membranes in any members of this family. There is therefore no certain evidence that his cases belong to the class under consideration.

Family 2.—J. Wickham Legg in 1876 read a paper before the Royal Medical and Chirurgical Society of London on a Case of Hæmophilia complicated with Multiple Nævi.[4] The patient, a musician, aged 65 years, had been subject to epistaxis from boyhood and had also shown a tendency to bleed from traumatic causes. He had numerous small nævi over the face, forehead, and various parts of the trunk which had been first noticed when he was about 41 years of age. Several members of his family suffered from epistaxis.

Family 3.—O. Chiari[5] in 1887 described the cases of two sisters, many of whose relations suffered from recurrent and severe epistaxis. He at first thought the spots on the mucous membrane in these two cases were telangiectases, but after observing two other cases he came to the conclusion that in all four cases he had to deal with blood extravasations undergoing a slow change, such as might be met with in hæmophilic patients. Brown Kelly shows reason for doubting the presence of hæmophilia in Chiari's, as also in Wickham Legg's cases.

Family 4—Rendu[6] at the Société Medicale des Hôpitaux de Paris in 1896 brought forward the case of a man, aged 52 years, suffering from repeated epistaxis. He had small superficial angiomata of the skin of the face, neck, and thorax, and of the mucous membrane of the mouth. Angiomata were not actually seen in the nasal passages, but it was presumed that some were present there also and accounted for the frequent attacks of epistaxis There was a history of repeated epistaxis in the patient's mother and in one brother. The latter, however, had suffered from albuminuria. The patient's father had died from "dysentery" and had been subject to melæna.

Family 5.—The first two cases described by Osler[7] were those of brothers, aged 57 and 55 years respectively. There was a history of repeated epistaxis in their father, two sisters, the child of one of the patients, and a grandniece. The face of Osler's elder patient "presented a very unusual appearance owing to the large number of dilated venules and capillary and venous telangiectases." There were numerous angiomata on the mucous membrane of the nasal septum and on the tongue. The younger of the two patients had likewise cancer of the stomach and died in the hospital. Sections of the septum of the nose from the latter case "showed many large dilated veins just beneath the epithelium"

Family 6.—Osler's third case[8] was that of a man, aged 49 years, who had been subject from childhood to attacks of epistaxis which recurred at short intervals. Except for the epistaxis he had been a healthy man. There were multiple telangiectases of the skin and of the mucous membranes of the nose and mouth. In this case cauterisation of the angiomata on the nasal septum seemed at one time to do good. So far as the patient himself knew "there were no bleeders in his family and none of the members had had serious attacks of epistaxis."

Family 7.—C. O. Hawthorne[9] has recently published a short note of the case of a woman, aged 49 years, with bright red telangiectases scattered over both cheeks and with a few on the fingers of the right hand. She had been subject to repeated epistaxis from childhood. Her father and a sister were troubled in the same way and both of them, as well as her eldest daughter, had "spots" like those on her own face. All her nine children had had more or less numerous attacks of epistaxis.

Family 8.—Brown Kelly's patients[10] were two sisters, aged 41 and 40 years respectively. Their father had been subject to attacks of epistaxis and vomiting, and he had "spots" on his face similar to those on their own faces; he was said to have died at the age of 62 years in consequence of frequent bleedings from the nose. The elder of the two patients died suddenly from syncope induced by severe epistaxis. A daughter (aged 23 years) of the elder patient had lately also developed telangiectases on her face. In Brown Kelly's patients, as in some of the other recorded cases, it does not appear that the telangiectases were present in early life. In fact, the obvious angiomata on the skin in these cases, as Brown Kelly points out, are not usually observed until the patient is approaching middle life, and "the most striking development of the telangiectases seems to take place from the age of 35 or 40 onwards."

Dr. W. Bligh[11] says that a man, aged 32 years, required his assistance on account of bleeding from the left forearm. On examination the source of the hæmorrhage was found to be a minute nævoid growth, from which arterial blood was spurting freely. Similar nævoid growths were present on the back of the left wrist, on the side of the neck, and on the forehead. The growths varied slightly in size, but the largest was no bigger than the head of a "carpet pin." He had been previously troubled with violent bleeding from more than one of the little tumours Dr. Bligh destroyed all the little growths by cauterising them, but a few months later bleeding occurred from a fresh tumour on the face; two other fresh ones had likewise appeared upon the forehead. These were all destroyed in the same way. The patient was healthy and not hæmophilic. Dr. Bligh has kindly informed me that there is no history of angiomata in the family of his patient, but nevertheless I mention the case here as it is well known that usually "familial" diseases do occasionally present themselves in an apparently isolated fashion.

Though Dr. Bligh's case may not belong to the group under consideration it is a remarkable example of the kindred condition of multiple late developmental angiomata. An equally striking example of the latter condition is furnished by a case shown by Dr. F. J. Smith at the Medical Society of London on April 4th, 1898.[12] Dr. Smith's patient was a woman, 50 years of age, with multiple venous angiomata chiefly on the face and upper part of the trunk, varying in size from that of a pea to that of a small bean. In addition she had varicose veins of both lower extremities and both labia majora. Nine months previously, according to the patient's own account, she was perfectly well and had no varicose veins even in the legs. About that time she noticed a small painful spot on the right side of the nose, which came up like a small red pimple; soon after this some other red spots appeared on the back and shoulder and these spots later became bluish. In the case of a middle aged man shown at the Dermatological Society of London on Dec. 12th, 1900,[13] with multiple bluish nodular angiomata on various parts of the body and face, there was a decided family history of multiple venous angiomata. Some of his little tumours dated from birth, others had the Midwives Roll (1906) is 23,278, and the total number of births registered in England and Wales in 1906 was 934,391; so that if all the certified midwives were in practice there would have been only about 20 cases for each, assuming that about 50 per cent. of the births were attended by medical practitioners. On the other hand, a number of certified midwives do not practise as such but are engaged only in general and monthly nursing and the returns before us suggest that the proportion of actually practising midwives may be estimated as being about 62 per cent. of the whole number, or about 14,430. And on this estimate there would have been about 33 cases for each midwife actually in practice, representing a gross annual income of about £16 10*s.* Whilst this applies to England and Wales as a whole the demand for the services of midwives varies considerably, as one would expect, in different localities according to the prevailing social conditions. Thus, in Group I. of our tables we find that the average number of cases in the year to each practising midwife is nearly 18. The preceding applies to the state of things in smaller urban and in rural districts; in the large boroughs included in Group III. the average number of cases to each practising midwife rises to 61. We believe that the fee paid to a midwife in rural districts varies between 5*s.* and 10*s.* a case, but rarely exceeds 8*s.*; in towns the fee would appear to vary from 5*s.* to 15*s.*, but 10*s.* per case would seem to be a fair average. And under these conditions it is obvious that comparatively few of the midwives who are in practice can be earning a living wage by direct payment from patients. Under the conditions prevailing in sparsely populated rural districts we feel convinced that it is simply impossible for a midwife to earn a living wage, or anything approaching a living wage, unless she is working under a county or other charitable association."

[13] I cannot find the account o thi case in British Journal of Dermatology

Dealing with the same question Miss Alice Gregory, who has herself been in private practice for eight years in a rural district, writes as follows:—

> If we take a 10*s.* fee as the suitable average to be charged in the future and 150 cases as the limit that can be properly attended by one midwife in a scattered country district, it is evident that she can earn £75 (a living wage, though a bare one) in every area where this number of cases may reasonably be expected. 23 in 1000 is a fairly low average birth-rate. Of these the midwife cannot, under the most favourable circumstances, expect to attend more than 18, and of these, some she will attend as a monthly nurse under the doctor (though always on the same basis of daily visits as her other patients). We see therefore that a strong woman, *who is a good cyclist and popular with her patients*, may anticipate the probability of earning her own livelihood in every district where she can reach a population of 8000 within four miles in every direction from her own home. It will take her from five to ten years to work up such a practice and during that time she will *not* be earning her livelihood but will need assistance.

Almost every medical officer's report seems to show that in spite of a certain economy in numbers which will be made possible when well-trained and more active midwives are employed, the number of cases for each midwife will remain too small to enable her to be self-supporting. It is owing to this fact that in the large and sparsely populated districts the Act is at present being administered so gently. In Manchester there is one midwife to every 3600 persons; in Shropshire there is one to every 700 persons. In Derbyshire the gentlest administration of the Act has been found necessary amongst a very illiterate and unsatisfactory class of midwife in order to retain sufficient women for the needs of so sparsely populated a county. In the rural districts of every county the best is being made of bad material, since it is impossible for the trained midwife to make a living out of midwifery alone.

Having answered the questions submitted to it so far as was possible from existing information the subcommittee, with a view to supplement that information, issued on Dec. 5th, 1906, schedules of inquiries to local supervising authorities. Amongst the subjects of inquiry were: (1) the number of certified midwives resident in the several areas; (2) the number of certified midwives who are actually practising; (3) the proportion of practising certified midwives who are engaged in public and in private practice respectively; (4) the proportion of births attended by medical practitioners and by certified midwives respectively; and (5) the means of subsistence of certified practising midwives. The schedule of inquiries was sent to the 134 local supervising authorities in England and Wales, of which 62 are county and 72 are borough authorities. Replies were received from 40 county and 60 borough authorities. In addition to these, replies were received from various urban and rural local authorities acting under delegated powers in Dorset, Kent, and Lincoln and from the municipal borough of Woolwich. The population of the areas to which these returns apply is estimated as having been 24,413,738 at the middle of the year 1906—i.e., at a time when the total population of England and Wales was estimated by the Registrar-General as being 34,547,016.[*]

Taking the subjects of inquiry one by one the results may be summarised as follows.

1. *The number of certified midwives resident in the various areas.*—The total number of certified midwives returned as resident in the areas concerned (with an estimated population of over 24,000,000) is 12,494; of these, 2948 are trained, 6803 are untrained, and with regard to 2743 no information is given. It may be assumed that the majority of this last group are untrained. These returns, however, are obviously not quite accurate. In some instances the returns give merely the number of midwives who had given notice of their intention to practise within the areas. From the figures given in the last edition of the Midwives Roll (July, 1906) and from other data it is estimated that the number of midwives resident in the areas concerned is probably about 16,600 instead of 12,494 as given in the returns.

2. *The number of certified midwives who are actually practising.*—The total number of practising certified midwives in the areas from which returns have been received is 10,407. This figure is probably correct. Supposing that the number of resident midwives is 16,600 (see preceding paragraph) the percentage actually engaged in practice is 62·6. Some of these attend very few cases, less than half a dozen perhaps in the year.

3. *The proportion of practising certified midwives who are engaged in public and in private practice respectively.*—Out of a total of 10,407, 105 were employed in hospitals, 669 were employed by county, district, and other associations, 148 were employed in Poor-law work, 4128 were engaged in private practice, and with regard to 5357 no information is given. Of this last group it is fairly certain that an overwhelming majority were engaged in private practice.

4. *The proportion of births attended by medical practitioners and by certified midwives respectively.*—Of the 195,774 births occurring amongst an estimated population of 7,227,493 in the areas (Groups I. and III. on Table) as to which closely accurate information has been obtainable, the number returned as attended by medical practitioners is 100,889, or about 52 per cent., and the number attended by certified midwives is 94,885, or about 48 per cent. As the percentage attended by medical practitioners has in some instances been arrived at by crediting *them* with all the births not known to have been attended by certified midwives it is certain that it is over-estimated. The actual proportion of births attended by medical practitioners in England and Wales is probably under 50 per cent. The number of cases attended by midwives varies considerably in different areas, from about 90 per cent. of the total births in one district to "almost none" in others. Speaking generally, the proportion of births attended by midwives is highest in the industrial districts and lowest in agricultural districts.

5. *The means of subsistence of practising certified midwives.*—On this point it has only been possible to obtain very scanty information. Thus no information at all was forthcoming as to 7611 midwives out of the total number of 10,407. Of the remainder 1162 were married women who supplemented their incomes by attending midwifery cases, 706 combined midwifery with other work, whilst 928 made their living by midwifery alone. It must not, however, be supposed that this last group maintained themselves entirely by private practice as a considerable number of them were in the employ of various charitable associations. Of the 7611 as to whom no information is given it is probable that a very large majority are married women who merely supplement their incomes by attending midwifery cases.

The difficulties here shown to exist in regard to the possibility of a trained midwife earning a livelihood in private practice in rural districts are met with also in connexion with the various local associations, which are frequently only able to offer very small and inadequate salaries for the services of a district midwife. The association that initiated the present inquiry has been confronted with this after 48 hours and the other symptoms gradually got less severe and by April 16th he was quite convalescent. A tonic mixture was then given and by April 20th he was cured. There was no desquamation.

---

[*] Returns were also received from Cornwall, Leicestershire, and Southampton, but these being incomplete were not included with the rest.

In this case it is somewhat difficult to decide whether the initial pain complained of resulted from the injury to the shoulder or whether it merely heralded the onset of the herpes zoster, the fall either precipitating the onset of the herpes or drawing the patient's attention to the pain. The attack of influenza which subsequently supervened is interesting because it was accompanied by a rash, a rather uncommon though not unknown occurrence. That it was influenza is proved because several people who came in contact with the patient contracted influenza and the nurses in attendance developed influenzal colds. The rash, too, had not the characteristic distribution of scarlet fever and there was no subsequent desquamation.

Kidderminster.

A CASE OF SUPERNUMERARY DIGITS.

BY WILFRID H. W. ATTLEE, M.D.CANTAB., M.R.C.S.ENG., L.R.C.P. LOND.

THE accompanying illustration of the hands of a newly born male infant may be of interest. On each hand there was an extra digit attached to the ulnar side of the little finger by a soft pedicle consisting only of skin and blood-vessels.

Reproduction of photograph of infant's hands showing supernumerary digits.

Each digit had a well-formed nail. In all other respects the hands were normal. The child's parents are first cousins and one of their uncles had a supernumerary thumb on one hand. This man would be the infant's great-uncle.

Eton.

Medical Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on July 11th, Mr. W. D. Spanton, the President, being in the chair.—Dr. J. Hutchinson Swanton showed a specimen of Fibromyoma of the Vagina and read notes of the case. This occurred in a widow, aged 40 years, who gave a history of five pregnancies and four abortions, the last being five years previously. The clinical history was one of endometritis. The tumour was discovered in routine examination high up on the anterior wall and presented no symptoms. Removal was recommended as it increased in size recently. It was found to be a pedunculated fibromyoma measuring three-quarters by one-third of an inch.—In the discussion which followed Dr. H. Macnaughton-Jones said that such tumours were comparatively rare. It was important to know whether they became degenerated or malignant. Such growths were sometimes sarcomatous.—Professor J. W. Taylor had met with similar growths four times and in one instance it recurred three times after removal, although on examination presenting the histological characters of a myoma.—Dr. J. J. Macan raised an interesting point in the pathology of these tumours. —The President said that the question centred around the possibility of these growths becoming malignant.—Dr. Swanton also showed a specimen of Cystic Adenocarcinoma of the Ovaries and Vermiform Appendix removed from a patient, aged 69 years, originating in cystic growths and becoming malignant.—The President remarked on the extreme malignancy of these growths when arising in such a manner.—Dr. A. E. Giles commented on the diagnosis and said that carcinoma of the ovary was not often directly diagnosed, especially where there was no free fluid.—Dr. Macnaughton-Jones considered that the prognosis depended upon the escape of carcinomatous fluid into the peritoneum or not.—Dr. Macan said that malignant disease very frequently involved both ovaries, although not in an equal degree.—Dr. E. A. Neatby wished to know whether ovarian carcinoma occurred more frequently as a primary or secondary condition. He related an interesting case where recurrence took place in the adjacent intestine some months after removal of the ovarian tumour.—Dr. Macnaughton-Jones showed a specimen of Large Myoma removed from an unmarried patient, aged 32 years, who complained of menorrhagia and secondary anæmia. The growth was encapsuled by peritoneum and arose from the right of the body and cervix burrowing under the peritoneum. Another peculiarity was the presence of a lymphatic sac which seemed like the dilated and thinned-out body of the uterus undergoing degeneration. Both ovaries were removed as they were cystic and had degenerated.—Professor Taylor thought the cavity might be accounted for by the separation of layers of the peritoneum.—The President considered that the condition might be explained as being the result of peritonitis.—Dr. Swanton showed a Cyst of the Clitoris removed from a patient, aged 20 years, who thought that it was due to trauma and commenced three months previously. The growth was situated at the anterior extremity of the left labium minus, being three-quarters of an inch across. The clitoris and cyst were removed. The contents consisted of blood, pus, and sebaceous matter.—The President thought that such cases were rare and suggested that it might have had an origin similar to that of vaginal cysts.—Professor Taylor thought that the position was unusual and regarded it as a suppurating sebaceous cyst.—Dr. Macan said that such cysts were very rare. In the absence of further microscopical details it was difficult to decide as to the nature of the cyst.—The President then delivered his valedictory address and said that the amalgamation of the societies would act as an incentive to closer observation and more scientific methods. He hoped that the provincial members would come forward in the future as in the past. The death of the society meant but an entrance into a higher life of greater usefulness and enlarged opportunities in communion with similar interests. He then gave a *résumé* of the work accomplished by the society during the last 23 years. The first specimen shown was a multiple uterine myoma removed by hysterectomy. The view then expressed was that now held that to extirpate a tumour simply because it was a tumour which gave little or no trouble implied taking a responsibility on the part of the surgeon which he ought to decline. Other subjects discussed included matters such as asepsis, antisepsis, puerperal septicæmia, Porro's operation for cancer of the uterus, electrolysis in fibroid tumours as advised by Apostoli, myomata and pregnancy, morbid pelvic states and associated mental conditions, and displacement of the uterus and the use of mechanical supports. During the short session now brought to a close the subjects were of a practical nature and included uterine hæmorrhage, membranous dysmenorrhœa, prolapse of the uterus, inflammatory diseases of the appendages, mobile kidney, and the treatment of general peritonitis.—Hearty thanks were accorded to those who assisted in bringing about the amalgamation.—The meeting unanimously agreed—

> That we desire to record our appreciation of the courtesy and cordiality with which the Obstetrical Society of London united with our society in their arrangements for amalgamation.

—The meeting then terminated and the President signed the minutes.

EDINBURGH OBSTETRICAL SOCIETY.—A meeting of this society was held on July 10th, Dr. J. W. Ballantyne, the President, being in the chair.—Professor J. A. C. Kynoch (Dundee) read a paper on a Series of Five Cases of Cæsarean Section for Contracted Pelvis. Three of the patients had been born in Glasgow. The first patient was in her second pregnancy; in her first she had been delivered of a stillborn child by version, after repeated attempts with forceps in Walcher's position had failed. The true conjugate was about three inches, the pelvis being of the small, flat, rickety type. The case was unfavourable for the performance of induction of premature labour. The mother and child did well. The combined population of 4,677,883, from which the returns received were less ample.

Group V. includes various urban and rural areas situated in the administrative counties of Dorset, Kent, and Lincoln (part of Kesteven), and in the metropolitan borough of Woolwich with a combined population of 551,502.

Group VI. includes the administrative county areas of Cornwall, Leicestershire, and Southampton.

The populations of all areas are estimated to the middle of the year 1906, the number of births and the birth-rates in the respective administrative county areas are generally those for the year 1905, whilst the numbers of births for the county boroughs are those for 1906 as extracted from the Registrar-General's returns.

URBAN COTTAGES AND SMALL HOLDINGS IN THE GARDEN CITY AT LETCHWORTH.

THE Garden City at Letchworth, Herts, grows apace and its first inhabitants are beginning to realise that a great town planned on artistic and hygienic lines is being rapidly developed around them. The interest of the public in the question of rural depopulation and urban congestion was stimulated in a practical manner by the Cottage Exhibition which was held in the Garden City in 1905. On that occasion the exhibition was limited to cheap cottages for rural workers and the use of temporary materials for building was permitted. The cottages were isolated and suitable for districts where large areas of land were available.

The present exhibition comprises cottages built under urban by-laws and at prices which will render it quite possible for exhibitors to combine economy with efficiency of construction and a class for homesteads suitable for small holdings. Prizes are offered for four classes of cottages, the cost ranging from £175 to £240, while a further prize is offered for the best artisan's cottage which is not limited as to cost. In regard to small holdings prizes are offered for (*a*) the best cottage with simple outbuildings suitable for small holdings of five acres, the cost not to exceed £200; (*b*) cottage with barn, stable, cartshed, and pigsty, suitable for a small holding of 20 acres of arable land, the cost not to exceed £250; and (*c*) a small holder's house (to contain dairy) with pigsty, shed, and cowhouse for two cows, the cost not to exceed £300. As regards the urban cottages, the conditions were that they must contain larder with outside window, water-closet and bath, and have gas and water fittings ready for connexion and drainage to the main sewer provided. The height of the rooms was to be not less than 7 feet 6 inches. The cottages in the small holdings section were to comply with rural building by-laws and to contain three bedrooms, water fittings, larder, and outside earth closet. The statements as to cost of building are guaranteed by the fact that the condition of entry into the exhibition is that the exhibitor shall, if called upon to do so, sell the cottage to the Garden City Company at the price stated in the catalogue, or shall undertake, if called upon to do so, to build a similar cottage at the same price for the company reasonably near and on the estate. The exhibition comprises over 30 different types of model cottages and will be formally opened by the Marquess of Salisbury to-day (Friday).

Briefly, the exhibition in its urban section is an attempt to show what may be done in an ordinary suburban street of any industrial town. An area of five acres only has been covered by 60 cottage sites grouped along complete streets with all the conditions of various aspects. The question of aspect is, of course, a difficult one when it is required to arrange rows of cottages with east, north, or west aspects in close proximity, but the designing of single cottages with a southern aspect is simple enough. The best, however, has been done, and it is most pleasing to observe the regard that has been paid to artistic effect, to the elimination of monotonous lines, to the economy effected as regards frontage, and to the exclusion of "built-up backs" and long projecting sculleries all conspiring to block out the light and air from the living rooms. Here is a useful demonstration of how the evils of overcrowding may be banished from our midst, of how the solution of the slum problem may be reached, and of how sanitation may be secured for the masses as well as the classes.

Letchworth is growing rapidly as an industrial centre. Already 11 factories have been erected and there are now between 3000 and 4000 people settled on the estate. It is not intended that the garden city shall ever grow to a town of a greater size than will accommodate 35,000 people and when this stage is reached development will stop so far as the city is concerned. When this consummation is attained the busy city will still be situated in an environment of fresh air and light. It must be admitted that the Garden City is a very interesting sociological experiment to which everyone who cares at all for the social and sanitary welfare of all classes, but especially the poorer working classes, will heartily wish success.

THE HAMPSTEAD GENERAL HOSPITAL.

ON July 16th an extraordinary general meeting of the governors of the Hampstead General Hospital was held in one of the large wards in the recently completed and unoccupied new wing of that institution. We have already recorded the events leading up to the controversy concerning the constitution of the staff of the hospital and the many other points at issue, the chief of which are the question of amalgamation with the North-West London Hospital and the relations of the hospital's council to King Edward's Hospital Fund for London, to the body of subscribers, and to the local medical practitioners. The difficulty of this complicated situation and the vital effect that the solution which is to be adopted will have on the welfare of the hospital are fully recognised by the governors and found expression in a meeting numbering at least 200 ladies and gentlemen, all of whom have at heart the best interests of the institution.

The chair was occupied by Mr. EDWARD BOND who pointed out the gravity of the occasion and reminded the meeting that although it had been convened in protest against the council's action in accepting the terms of the King's Fund for a scheme of amalgamation with the North-West London Hospital and thereby agreeing to the replacement of the staff of local practitioners by one of consultants, yet that the council had acted within its rights as set forth in the articles of association of the hospital in so doing, and that any adverse resolution passed by the meeting would have no legal binding power on the council, although it would doubtless carry great moral weight.

Mr. ERNEST COLLINS, the chairman of the council, then detailed the protracted negotiations that had taken place with the King's Fund and claimed that the council had consistently and loyally supported the present staff and also the best interests of the hospital. He examined at length the financial advantages to the hospital under the amalgamation scheme and stated that at the very lowest estimate, after writing off a liberal sum for the added expense of keeping up the North-West London out-patient department, the Hampstead Hospital will gain a clear increase of £1500 a year income.

The MAYOR of HAMPSTEAD (Councillor C. HENDRICK) then rose to move:—

> 1. That the practice, hitherto followed, of appointing acting medical officers from among the members of the medical profession practising in Hampstead be continued.
>
> 2. That the number of physicians and surgeons on the consulting staff be augmented.

In a vigorous speech, though the vigour would have gained by some curtailment, he criticised severely Mr. Collins' estimate of the added revenues under the amalgamation scheme; he put these at a much smaller figure than £1500 and insisted that the great pride of the Hampstead Hospital was in being a local institution for Hampstead people. They did not, he said, want to emulate the big London hospitals and they greatly preferred in the interests of the patients to have such an excellent staff of local practitioners as they had at present to a staff of consultants who would not be of the first rank and who would live far away. He considered that if the proposed change was made much local support would be lost. He denounced the council for having shown a vacillating spirit and for having submitted too readily to the King's Fund, and accused it of exceeding its duties in having made such a revolutionary change in the hospital's affairs without reference to the body of subscribers. Although the Mayor was interrupted by some adverse ejaculations yet during his speech plaudits were much more frequent, and it certainly seemed that he had the sense of the meeting with him.

turn will depend on the material used up in connexion with muscular work. The energy may come from all three classes of organic foodstuffs. Even in fasting animals, where the store of carbohydrate is more or less used up, severe muscular work causes no little appreciable increase of nitrogen output, showing fat as the source of the energy; indeed, only about 1 per cent. of the animal's proteids is eliminated each day.

The latter half of the volume deals with the "*true* nutritive requirements of the body." According to the author, arguments based on the dietetic customs and habits of mankind are not to the point, nor are instinct and craving wise guides to follow in the choice and quantity of food. Direct physiological experiment is the guide to the "ideal diet" (p. 165). The author cites his own observations on proteid diet already published, such as those on 20 men from the Hospital Corps of the army, and again he comes to the same conclusion as before that the body weight and nitrogen equilibrium can be maintained on an amount of proteid food far below the fixed dietary standards. University athletes are then referred to, and the results of Fischer of Yale on strength as distinguished from endurance are considered, and the same conclusion is arrived at as regards the reduction of proteid food. Overfeeding is the predominant dietetic sin. As to resistance to disease, the author has no evidence that this is diminished on his reduced proteid diet. A new group of experiments on dogs to test the effect of low proteid diet on high proteid animals is detailed and the results again confirm the author in his opinion. It will be seen, therefore, that the author maintains his position as to the excessive amount of proteid even in our "normal" and "standard" dietaries. This work is largely a reflex and extension of his previous volume.

Archives of Neurology. By F. W. MOTT, M.D. Lond. London: Macmillan and Co., Limited. Pp. 626.

THE third volume of the "Archives of Neurology" of the Pathological Laboratory of the London County Asylums, consisting of the record of work done by Dr. F. W. Mott and by assistants under his direction, is a most notable achievement. Dr. Mott has truly founded a school of pathology in this country, and as his opportunities are great so has he taken corresponding advantage of them. The London County Council, in applying its money to the maintenance of research work and in not stinting the means at its disposal, is in reality doing the work of a State-aided academy, and by these published results it justifies its confidence in the zeal and diligence of its officers who, relieved of departmental and economical worry, are able to carry out investigations in the true scientific spirit untrammelled by perfunctory monotony.

Of the 26 chapters in the book 15 are written by Dr. Mott (one, however, in conjunction with Dr. W. D. Halliburton) and 11 by others connected with the laboratory. Some of these chapters are in reality essays, involving much time and laborious investigation, and whilst some are sufficiently distinctive to constitute a life-title for excellence in research work, others may be characterised as distinguished, whilst none are mediocre. Merely to name the subjects of the various contributions is unnecessary because our limits do not allow us to criticise them all, but we may call especial attention to three of them—viz., the Mammalian Cortex, with Special Reference to its Comparative Histology, the Suprarenal Glands in Nervous and other Diseases, and the Effects of Alcohol on the Body and Mind as shown by Asylum and Hospital Experience. The first named of these is the "Bowman Lecture," founded on work done by Dr. Mott in the laboratory at Claybury. It is an epoch-marking contribution and by itself stamps the originality and profundity of the author. The second article, written in conjunction with Dr. Halliburton, is of great interest not only to those concerned with the treatment of insanity but to general physicians, whilst the third is of immense importance for every practitioner of medicine.

One chief value of the work is the model that it provides of what can be done by the personality of a central director in associating with himself contributors and workers in many different directions, forming a totality energised in bringing its materials to elaborate the unity of the processes of disease in all parts of the body.

The book is not for everyone to understand. To read it presupposes a large amount of training and special knowledge, and as it represents years of work so will it take a considerable time for assimilation, but it may be taken up at disposable moments and gradually incorporated, with the conviction that it relates facts to be stored up and not mere probabilities which do not merit the trouble of acquisition. There is nothing electric about the book, nothing startling in the shape of fascinating theories, but it is a solid piece of thorough work which may be safely used as an effective cantilever for further additions. Dr. Mott hopes that by more extensive collaboration it will be possible for sufficient research work to be produced to enable a volume to be published annually. We hope, however, that no pressure will be put upon the workers, no stress to produce a volume annually merely because so many months have elapsed. The drawings and photo-micrographs are of great excellence. We should prefer to find the leaves cut and we venture to suggest an index in future volumes.

Food and Hygiene. By WILLIAM TIBBLES, LL.D., L.R.C.P. Edin., M.R.C.S. Eng., L.S.A. London: Rebman, Limited. 1907. Pp. 672. Price 8*s*.

"FOOD and hygiene" is a well-nigh inexhaustible subject and anyone dealing with it must realise the difficulty of keeping his observations within such limits as not to exceed the space usually allotted to a text-book of average size. The chief merit of the book before us is that the author has contrived to cover a good deal of ground within the limits of a volume which is decidedly less bulky than are many standard works on the same subject. In doing so he has sacrificed on the whole very few, if any, essential points. He has in particular succeeded in conveying to the reader the relations between food and health. Starting with some generalisations on food in its relation to the wear and repair of the body, he prepares the reader with a good priming of physiological and chemical knowledge so far as they bear on the great metabolic processes. Next he introduces him to the materia alimentaria in 11 well-written chapters, the two chapters at the end of this section dealing with water, air, ventilation, climate, clothing, and so forth. In the chapter on stimulants and narcotics he acknowledges drawing a good deal of material from the pages of THE LANCET. He quotes, for example, numerous analyses of wines and spirits which have been published from time to time in our columns. We may be excused for pointing out that some of the figures are incorrectly printed; the higher alcohols for "three star" brandy should read *120·68* and not 12·0, while the footnote incorrectly states that the secondary products are reckoned in grammes per litre. "Per litre" should read *per 100 litres of absolute alcohol present*. The chapter on water, though short, sums up the situation very well in the light of modern knowledge and of course includes a reference to the share which bacteriology and chemistry take in elucidating questions of the fitness or unfitness of water for drinking purposes. We must, however, point out one mis-statement in this section. In describing the simple test for the presence of organic matter in water, which consists of adding some permanganate of potassium to the water and observing whether the colour the Association week, suggested by the late Dr. G. Bagot Ferguson of Cheltenham, by whom the first was delivered in 1904, will be given this year by Sir John William Moore of Dublin, who will speak on weather, climate, and health, illustrating his subject by a large number of screen and lantern slides. The temporary pathological museum promises not to fall behind any of its predecessors; and the usual annual exhibition of foods, drugs, medical and surgical instruments, sanitary and ambulance appliances, &c., will be open on each day except Saturday from 9 A.M. to 6 P.M.

The arrangements for the social side of the meeting have not been neglected. On Tuesday afternoon the Mayor of Exeter will give a garden party; on Wednesday afternoon garden parties will be given by the President of the South-Western branch, Dr. P. M. Deas, and by Dr. D. W. Samways; on Thursday afternoon Sir Thomas Dyke Acland will give a garden party, and Mr. G. G. Gidley, Cullompton, will entertain a picnic party at tea; on Friday afternoon the High Sheriff of Devon, who is also President of the Royal Devon and Exeter Hospital, Sir Dudley Duckworth King, will give a garden party at Wear House; and there will be luncheon parties at Teignmouth, Torquay, and Sidmouth. On Wednesday evening there will be a reception by the South-Western branch on Northernhay; and on Friday evening the civic authorities will hold a reception in the Albert Memorial. The annual dinner of the Association will take place on Thursday evening and on the same evening ladies accompanying members will be entertained at the theatre by the ladies' committee. Excursions have been arranged to visit Devonport Dockyard; the Station Hospital, Devonport; the Royal Naval Hospital, Plymouth; the gunnery, torpedo, and training ships; and Plymouth Sound and the River Tamar. Those taking part in the last-mentioned excursion will be entertained at tea by the Earl of Mount Edgcumbe. Other parties will visit Falmouth and Ilfracombe; others Bideford and Clovelly, where they will be entertained by Mrs. Hamlyn of Clovelly Court; and others Tavistock, driving thence to Endsleigh, where they will be entertained at luncheon by the Duke of Bedford.

MEDICINE AND THE LAW.

Fracture of the Thyroid Cartilage.

FRACTURE of the thyroid cartilage is sufficiently uncommon to warrant notice of the following case tried before Mr. Justice Sutton at the Staffordshire summer assizes on July 12th last. James Lees, aged 33 years, a powerfully built man in the employ of the Burton Brewery Company, was indicted for the manslaughter of a fellow employee, named Henry Townsend, on June 12th. Mr. D. Cotes-Preedy, for the prosecution, stated that about 10.50 A.M. on that day the two men quarrelled. Lees struck the deceased two blows on the face and one on the neck. Five minutes later Townsend went to a friend near by with his nose and mouth bleeding and voice very hoarse and made a complaint. Dr. R. A. H. Atkinson, house surgeon to the Burton Infirmary, said that the deceased was admitted at 12.15 P.M. on the same day. The left cheek was contused and the inside of the lower lip was cut. On examining the neck a distinct grating was felt over the region of the left half of the thyroid cartilage, which pointed to a fracture. There was no external mark to correspond, but there were two small abrasions on the side of the neck. Townsend's voice was husky and indistinct. During the first day after admission the patient had half a dozen attacks of dyspnœa, and on the following day three attacks. His condition did not improve and on June 14th delirium tremens supervened with intervals of consciousness. To relieve the dyspnœa tracheotomy was performed on June 16th, but the patient sank and died on the same day. Townsend was a fairly healthy man. A post-mortem examination was made shortly after death by Dr. Walter George Lowe, of Burton-upon-Trent. There was a fracture of the left half of the thyroid cartilage. The vocal cords were still swollen. The lungs and right side of the heart were engorged with blood and the latter organ showed signs of commencing degeneration. The liver was rather fatty. In the witness's opinion death was due to asphyxia and heart failure brought about by the fracture of the cartilage. Both medical men agreed that such a fracture was most rare and that in all probability a severe blow must have been struck to cause the injury. For the defence Mr. Sherwood stated that the deceased man had threatened Lees with a shovel and pleaded for leniency on the ground of the latter's excellent character. His lordship bound Lees over in his own recognisances to come up for judgment if called upon.

The Fast Driving of Motor-cars.

It will have been observed by many drivers of motor-cars that one of their number was sentenced at the recent assizes at Chester to nine months' imprisonment in the second division for manslaughter by negligently driving over and killing a man. The Lord Chief Justice who tried the case pointed out, in sentencing the prisoner, the grave danger necessarily occasioned by the reckless driving of motor-cars and observed that it appeared not to be realised sufficiently that when a machine of such a nature was driven along a public road the lives and property of others must be respected by the person in charge. At present there have been a good many deaths caused by motor-cars and comparatively few convictions for manslaughter, but many motorists seem to think that the increase in the maximum speed permitted to them by law enables them to drive at a pace approaching 20 miles an hour with safety wherever they are. A large number of motor-cars are to be seen daily in the streets of London travelling at a pace which may cause a serious accident at any moment, and the fault will be that of the driver, should one take place, even though something beyond his control may be immediately responsible for the occurrence. The owners of private motor cars incur a heavy responsibility in allowing or causing their chauffeurs, where these are employed, to drive at excessive speeds for the sake of convenience or pleasure. It may also be observed occasionally that familiarity with their work is beginning to breed contempt of danger in the breast of the driver of the motor-omnibus. Where these belong to rival companies, the spirit of competition is already leading to something very like racing, and when two or more motor-omnibuses are racing in a London street any accident that may occur is likely to be a very severe one.

ASYLUM REPORTS.

Surrey County Asylum, Brookwood (Annual Report for the Year 1906).—On Jan. 1st, 1906, there were 1341 patients on the register of the asylum; of these, 542 were males and 799 were females. During the year 393 (174 males and 219 females) were admitted and Mr. James E. Barton, the medical superintendent, again draws attention to the incurable types of insanity from which many of these were suffering. The average age on admission was 43 years and 86 patients were over 60 years of age, which is strong proof of the large number of senile cases received into the county asylums. Of those discharged during the year 112 (54 males and 58 females) were "recovered," 37 (ten males and 27 females) were "relieved," and 102 (58 males and 44 females) were "not improved." The death-rate, calculated on the daily average number resident, was 11·26, which is higher than the previous year, but 69 out of the 155 patients who died were over 60 years of age. A few cases of dysentery and erysipelas are reported. This asylum, as is the case with so many county asylums in this country, was much overcrowded during the year and a contract was arranged with the Oxford Asylum for the reception of 40 males and 20 females and with the York City Asylum for the reception of 30 females, but great difficulty was experienced in finding the class of cases suitable for transfer owing to the restrictions imposed in the contract and also to the Commissioners in Lunacy insisting that only the patients who were never visited by friends should be sent. At the end of the year the number of patients boarded under contract with other asylums was 130—viz., at Dorset, 40; at Exeter Borough, 10; at Oxford, 60; and at York, 20. There were 11 patients who escaped during the year and of these 10 were recaptured within the statutory period. Most of the escapes took place among those working in the farm or gardens. The Commissioners in Lunacy note in their report "that they were glad to see the children segregated from the adults on both sides, in small wards of 11 girls and three boys on the female side and 13 boys on the male side." The weekly maintenance rate for home county patients was 12s. per head. The farming and gardening account shows a credit balance of nearly £600.

nerves cause the whole bladder to contract, in some, as the cat and rabbit, they also inhibit the sphincter. Hence the nervi erigentes, or pelvic visceral nerves, springing from cells situated in the sacral segments of the cord below the lumbar enlargement, are the nerves of micturition. In the cat, and in a less degree in the monkey and pig, the hypogastric nerves, which have a root origin above the lumbar enlargement, constrict but do not shorten the urethra and relax the bladder. They are nerves which promote retention of urine. They do not have this action in man. Automatic rhythmic contractions practically only occur in bladders supplied with inhibitory nerves. In the dog the hypogastrics control only a very small area at the base of the bladder close to the sphincter. Universal inhibition of the bladder as in the cat is not observed. Variations in the extent of area innervated by the hypogastrics are found to exist in different animals, being large in the ferret and male goat and small in the rabbit, female goat, and mongoose. The effects, immediate and remote, of nerve section are given. 2. The Functions of the Epiglottis and of the Glosso-Epiglottic Fossæ, by T. P. Anderson Stuart, M.D., Professor of Physiology in the University of Sydney. Professor Stuart supports the generally accepted view that in deglutition the larynx is closed by the whole organ, as may be felt by placing the finger on the pomum Adami which is then drawn upwards and forwards under cover of the base of the tongue. The epiglottis shows little or no movement. The arytenoid cartilages are first apposed to each other and somewhat raised, and then *together* they glide and incline forwards to come into contact with the epiglottis, movements that are facilitated by the disposition of the squamous epithelium covering their surface. The taste buds on the laryngeal surface of the epiglottis are true organs of taste. 3. The Regeneration of the Post-Ganglionic Vaso-constrictor Nerves, Part II., by Basil Kilvington and W. A. Osborne. The conclusion arrived at by these experimenters is that when the sciatic nerve of the dog is divided in the mid-femoral region and immediately sutured complete regeneration of vaso-constrictor nerves need not be expected prior to the 205th day. 4. Cholein in Cerebro-spinal Fluid, by Otto Rosenheim, M.D., lecturer on chemical physiology at King's College, London. 5. The Physical Properties of Horse Serum, by John Mellanby, M.A. 6. Metabolism during Starvation—1, Nitrogenous, by E. P. Cathcart, M.D. Glasg. These numbers of the *Journal of Physiology* contain also the Proceedings of the Physiological Society for March 23rd and for May 18th, 1907, as well as the index and title-page for Vol. XXXV., 1906–1907.

St. Thomas's Hospital Gazette.—The June issue contains the concluding section of the very interesting paper on Alcohol and Insanity, read by Dr. F. W. Mott, F.R.S., before the St. Thomas's Hospital Medical and Physical Society. The different types presented are discussed and a brief account is given of the structural changes met with in the nervous system in cases of alcoholic polyneuritic psychosis. The paper is illustrated by micro-photographs and diagrams. Lighter fare is provided in an amusing skit entitled, "A Hospital Appeal," parodying the methods of a leading representative of another hospital.

St. Mary's Hospital Gazette.—The June number contains the valedictory address delivered by Dr D. B. Lees, reviewing some of the opinions which are associated with his name. Thus, he emphasises the value of the ice-bag and bleeding in pneumonia and of the former alone in other inflammatory conditions. He accepts the micrococcus rheumaticus, or, as he here calls it, the rheumatococcus, as the proved cause of acute rheumatism and lays stress once more upon the dilatation of the heart which may occur in this malady as well as in diphtheria and influenza. He enforces the need for careful percussion of the cardiac area to ascertain the existence of dilatation of the different cavities of the heart, especially the right auricle and the left ventricle, and holds that salicylates often fail in rheumatic conditions owing to the employment of insufficient doses. Finally, he maintains that percussion is a most important aid in the early diagnosis of pulmonary tuberculosis, and that the treatment of this affection by inhalation of volatile antiseptics gives very gratifying results.

The Bristol Medico-Chirurgical Journal.—In the June number of this magazine Dr. J. Michell Clarke writes on Some Unusual Complications of Pneumonia, including peritonitis, thrombosis of vessels, endocarditis, nephritis and arthritis, and Dr. W. Kenneth Wills analyses 80 cases of Lupus Vulgaris, which he classifies under seven different types. Dr. Bertram M. H. Rogers records a case of Narcolepsy in a patient, aged about 30 years, who came of a neurotic stock, and Dr. F. Percy Elliott an instance in which compression of the aorta was successful in saving the life of a woman suffering from post-partum hæmorrhage.

The Bio-Chemical Journal. Edited by BENJAMIN MOORE, M.A., D.Sc., and EDWARD WHITLEY, M.A. Vol. II. Nos. 7 and 8. June 20th, 1907. University of Liverpool: Johnston Laboratories.—These numbers contain: 1. Allyl Sulphide, Some Aspects of its Physiological Action with an Analysis of the Common Leek (Allium porrum), by Wace Carlier, M.D., and C. Lovatt Evans. The authors found the composition of the leek to be: water and volatile oil, 88; fixed oil and glycoside, 0·65; resin, 0·48; organic acids and colouring agents precipitable by lead acetate, 1·10; sugars and extractives not precipitable by lead acetate, 2·24; gums and pectous substances soluble in water, 2·20; proteins, 1·55; pectous substances soluble in dilute NaOH, 1·69; cellulose, 0·77; soluble in B^{a} NH_4OH, 0·46; soluble ash, 0·72 (5 per cent. Cl); and insoluble ash, 0·14. The oil $(C_3H_5)_2S$ is yellow in colour, is absorbed with difficulty through the mucous membrane of the alimentary canal and skin, and is excreted by the lungs and skin, though not apparently by the kidney. In neurotic people garlic and onions act as an excitant. Allyl sulphide has no solvent action on uric acid or the urates. In rabbits the injection of 15 minims of a 1 per cent. solution of the oil caused in the first instance slight fall and then increase in blood pressure with reduction of the respirations from 51 to 39 and even 33 in the minute. 2. On the Effects of Acids, Alkalies, and Neutral Salts on the Fermentative Activity and on the Rate of Multiplication of Yeast Cells, by Eric Drabble, D.Sc., and Daisy Scott, M.Sc. The neutral salts of potassium and sodium fail when in small proportion to exhibit any marked inhibitory action on fermentation and the yeast cells reproduce actively in all strengths. Hydrochloric and nitric acids in strength 0·1 per cent. are fatal to the cells. 3. On the Phosphorus Percentage of Various Samples of Protagon, by A. C. Lockhead and W. Cramer, Ph.D. The authors found it to be 1·07 per cent. 4. Observations on the Behaviour of Opsonic and Serum Proteids during Pressure Filtration, by Warrington Yorke, M.B., Ch.B. Liverpool. The author finds that opsonins are not dialysable. 5. Heat Rigors in Vertebrate Muscles, by C. H. Vrooman, M.D., C.M. Winnipeg. The author finds that both the striped and unstriped varieties of mammalian living muscle subjected to a gradually rising temperature undergo two marked and comparatively sudden contractions, first, at about 47° C.; and secondly, at about 62° C. 6. The Conductivity of Blood in Coagulation, by T. M. Wilson.

HOUNSLOW HOSPITAL.—The question of the abuse of the out-patient department at this hospital is now under consideration by the committee of management, which has appointed a sub-committee to investigate the cases.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JUNE, 1907.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1907.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cerebro-spinal meningitis.	Total.	Annual rate per 1000 persons living. Including membranous croup.

enormous sites to allay the public dread as regards infection. All these things are not essential. There are to-day a large number of institutions constructed of wood or other cheap material which are affording opportunities for health and renewed vigour to numerous tuberculous patients who, were the £1000 per bed standard regarded as essential, would still be in their homes in the slums of large cities, and possibly in some instances infecting others with whom they lived. If these poor people are to be debarred from obtaining fresh air, food, and rest at a cheap rate by the requirement of standards necessitating at least 2000 cubic feet of space per bed, and walls around the site rising to seven feet, beyond which the patients are never to stray until death or "cure" releases them from bondage, *there is not likely to be much progress made* in the erection of sanatoriums, and if these unnecessary standards are to be made retrospective the majority of the sanatoriums must be closed and the patients sent back to their homes where, unrecognised and uncontrolled, they will await the final scene. It is to be hoped that no such restrictions will be imposed upon sanatoriums in which, so far as the evidence goes, the sick are not dangerous to the healthy. These are a few of the problems which are awaiting solution by the Local Government Board and we cannot say that we altogether envy it the task of determining what is practicable in the face of much which lacks the sense of proportion, more especially as at the same time it will be necessary to deal far more stringently with the food aspect of the tuberculosis problem, to control not only home-bred tuberculous milk and meat but also, to be strictly logical, the meat, cream, butter, and other dairy produce which reach us in such enormous quantities from other countries wherein we can inspect neither the cattle before slaughter nor the udders of the cows from which the milk is drawn.

◆

Athletic Championships and National Physical Development.

The winning of the Grand Challenge Cup at Henley for the second year in succession by a Belgian crew, the recent victories of Colonial football players, the success of M. Massey at golf, of Mr. Gould at tennis, and of Mr. Brookes at lawn tennis, with other similar incidents of athletic competition, have aroused a correspondence in various newspapers, contributed by writers who for the most part deplore these occurrences as if they were national calamities or symptoms of national physical decay. The coincidence of so many "championships" in athletic games being won within a short space of time by young men and women not of British birth may be without precedent, and to a limited extent may be due to all or some of the *various causes* which have been assigned to it by the letter-writers referred to—namely, to a growing "slackness" on the part of the British youth, to a tendency to look on at the *games* of champions, instead of partaking personally in such games without seeking any startling supremacy, or to a recently developed and increasing taste for cigarettes. It is, however, also possible to contend that these causes may have nothing to do with the matter or may only contribute towards it, or even to suggest that the loss of "championships" is not a national misfortune, and in part, at any rate, may be due to causes by no means to be deplored. If the failure to attain supremacy is due to the diminished numbers and *deteriorating quality* of the mass of healthy adolescents from which the ranks of the champions must presumably be recruited, we have a regrettable fact to deal with, but is it one which can be established? The champion oarsman, or cricketer, or golfer, or tennis-player is a being fitted by nature and educated by constant practice for the position which he and those who applaud him are prone, we suggest, to endow with an exaggerated importance. The falling off, if there be such, in the supply of athletes of championship standard may be due to a growing feeling that the importance of being a famous oarsman, or cricketer, or golfer, is one which, at any rate, is capable of exaggeration, and that those who devote themselves to a game between the ages of 22 and 40 to the detriment of their professional prospects may regret doing so when they compare themselves in middle age with contemporaries whose athletic feats were confined to their boyhood. Athletes of distinction have risen to high positions in after life, but such names as Wordsworth, Chitty, Denman, Brett, Lyttelton, and Reid revive memories of men whose constant and prominent participation in athletics ceased soon after they left college, at the age when a *young fellow has to choose whether he will give up a favourite pastime a few years before nature will compel him to do so, or will start in the race of adult life* heavily handicapped. We have mentioned the name of the headmaster of Eton and of his brother, the late Colonial Secretary, both among the most famous amateur cricketers of their day, and we might add that of Mr. A. G. Steel, K.C. None can say that these gentlemen, had they devoted themselves for several years to county cricket after leaving Cambridge, would have attained the positions which they now occupy, or can deny that their university degrees, which possibly have not affected their careers materially, would have been higher had not the cares of the University Eleven to some extent diminished the time which they were able to devote to study. After all, does it matter to them now if, after attaining a position in the world of games which their contemporaries will never deny them, they realised in time that a game is but a game and abandoned it in favour of the pursuits of manhood? If we have referred above to the amateur athlete only much of what we have said might be adapted to the case of the professional who early in life is exalted into a social and material prosperity apparently of a highly enviable nature, but who in after years frequently finds himself less well off than if he had applied his muscles and brains otherwise.

We confess that we cannot prove by any evidence that the defeats referred to in our opening paragraph *are due to* any marked diminution in the *general* reverence for athletic distinction. At the same time, however, we must point to a lack of evidence that they have been caused by a falling-off in the physical energy of the nation. We have invented certain games, being a people fond of athletic amusement, and others have learnt to play them as well as, or better than, ourselves. Why should they not?

Correspondence.

"Audi alteram partem."

THE APPOINTMENT OF SANITARY OFFICERS TO GENERAL HOSPITALS.

To the Editors of THE LANCET.

SIRS,—The necessity of sanitary supervision is recognised not alone in the construction but also in the practical everyday working of all institutions where large bodies of human beings are brought together—schools, factories, theatres, prisons, barracks, &c., and which are, or should be, regularly inspected by competent experts. If this care is needed in the case of the healthy it is much more so in those suffering from disease. The body under these circumstances gives off many more deleterious substances. The sick are more susceptible to disease germs than the healthy and the concentration of a large number of those suffering specially from the infectious disorders renders the infection not alone more potent but also more virulent unless the greatest attention is observed in keeping the ventilation and other sanitary arrangements as perfect as possible. These considerations are almost so self-evident that it is a matter of surprise that at the present time very few general hospitals have any expert advisers responsible for the many details included under the term of modern sanitation. No doubt in the more recently constructed buildings the ventilation, heating, and removal of excreta will probably be specially looked after, but this is only one aspect of sanitation and even these particulars are liable to go out of order if not kept under constant supervision. In many cases these details are left completely in the hands of the architect who lacks the knowledge needed which can only be acquired by a sanitary medical expert who has an intimate acquaintance with the daily working of these institutions. The ordinary medical attendants of the hospital have neither the time nor, in the majority of cases, the special training and experience to act as sanitary experts. Where so many purely technical questions arise it would be undesirable, if not dangerous, to place the decision of them in the hands of those who had not both special training and practical experience, nor do I think that the ordinary medical attendants would be anxious to add to their already laborious duties. No doubt in certain cases, as in the arrangements to prevent the spread of infectious diseases, the sanitary expert should consult with the general staff, but I do not fear any clashing in this respect. The general staff would recognise that the sanitary adviser was an important factor in aiding them in their efforts to cure.

Amongst some of the details the sanitary adviser would specially report upon would be the size of each ward and number of beds in them, the position of the beds, the lighting (natural and artificial), the heating, and, still more important, the ventilation so as to insure the purity of the air without draught, the accommodation for storing patients' clothes, the position, &c., of the outdoor department and dead-house, and the removal of the excreta and dry refuse. The excreta are often infected with the germs of contagious diseases and to permit them to be thrown into the closets without efficient disinfection is to infect the public sewers and through them the soil and water. I drew attention to this danger several years ago in a communication to the Liverpool Congress of the Royal Sanitary Institute and showed in how many cases the so-called disinfection of excreta was practically useless.

The many serious questions connected with the spread of infectious diseases in the hospital could be arranged in consultation with the general staff The carrying-out of the disinfection, &c., would be under the guidance of the adviser and the efficiency of the annual cleaning so as to insure the destruction of any dangerous germs should be under his direction. Lastly, I may refer to the important duties of the adviser in connexion with the food-supply of the hospital. I need hardly dwell upon the importance of a supply of pure unadulterated food to the sick, still in how many general hospitals do the general staff examine that food or could they be expected or be competent to form an opinion on the subject. For example, take one very largely used food—viz., milk. The milk-supply of unions, prisons, &c., is more or less kept under supervision and prosecutions for adulteration are not uncommon. Do cases of contamination of the general hospitals' supply ever come before the courts? Are we to understand from this that these contractors are always above suspicion or is it to want of any really efficient investigation and control? In the case of milk not alone should the supply be frequently tested but the contracts should have a clause permitting the adviser to visit and to inspect the dairies, cows, &c., at any time he thought fit. Outside the milk the meat, vegetables, and other food should be open to inspection and report by the adviser. I would be inclined to go further and permit him to give at least friendly advice on the cooking. It is no exaggeration to say that the cooking in many general hospitals leaves much to be desired, nay, reformed. The preparation of the diet of a sick person is not the least important element in effort at his cure.

I have perhaps said enough to justify my contention that the appointment of sanitary advisers to general hospitals would be public gain—alike beneficial to the patients, the general public, and the medical and surgical staffs.

I am, Sirs, yours faithfully,

July 6th, 1907. ANTONY ROCHE, M.R.C.P. Irel

GROCCO'S TRIANGLE: PHYSICAL AND ANATOMICAL EXPLANATION.

To the Editors of THE LANCET.

SIRS,—The objection urged by Dr. Alexander Morison against personal names as a basis of medical nomenclature is not the only one which he might have stated. There is a further drawback in the uncertainty which often exists as to priority of discovery. In this instance the names of v. Koranyi and of Rauchfuss have also been mentioned in connexion with an early clinical observation of the sign in question. It is significant that the name which Dr. Morison proposes is derived from pure Greek, which for more than 25 centuries down to the end of the last has been the recognised official language of *nosology*. At the same time, the alternative term "paravertebral," although it is a hybrid and a rather long word, is hard to beat as a "finder" But it is now probably too late to discuss a merely academical point. Practically the expression "Grocco's sign" seems to have already received its *imprimatur* in every language. Its brevity is tempting. Moreover, its use is conveniently free from awkward limitations. For instance, Dr. Morison states, and it was established by demonstration on the operating table two years ago, as communicated to THE LANCET in my postscript of July 22nd, 1905,[1] that the "paravertebral triangle of dulness" may be obtained as a result of an intra-abdominal as well as of an intrapleural collection of fluid and that the fluid may be pus just as it may be simple serous effusion. Further instances of this intra-abdominal causation have since then been obtained in a continuous series of cases of ascites. It is therefore essential that these alternatives in diagnosis should not be excluded in any name given to this physical sign which cannot be claimed as exclusively distinctive of intrapleural fluid.

In spite of these reservations, whenever there is obvious absence of any abdominal complication this sign is, in my experience, the most delicate test for the presence of free fluid in the pleural cavity. Neither the x ray nor ordinary percussion can succeed in proving whether after an attack of pleurisy the partial dulness which may persist at the base is due to fibrin, to fibrous adhesions, to thickening and inexpansion of the pulmonary tissues, or to a remnant of fluid. The needle itself is not a final appeal. "Dry tappings" have often occurred in cases diagnosed as of pleural effusion by means of the most trusted methods. Now and then one of these "dry tapped" subjects chances to die, and the post-mortem verdict may justify the physical signs against the needle. Professor Thayer[2] narrates a typically illustrative case—that of a previously aspirated effusion in which a few days later some basic dulness on *percussion* and the paravertebral triangle were to be got, but no fluid issued from the needle. Had the *crucial test* which I have introduced been applied in that case as in precisely similar cases in much deceived (*schwer enttäuscht*). Mr. CRACKANTHORPE supplies no substitute and gives no farther information or guidance to his disciples. That they will indeed be liable to be much deceived is, we think, well within the probabilities of the case. If a healthy man and woman, of procreative ages, are living together *maritalement*, it is evident that the births of successive children can only be prevented by complete or partial abstinence from intercourse (the latter, according to Dr. FOREL, being but an imperfect precaution), or by the use of artificial methods for the prevention or premature termination of pregnancy; and it is time that Mr. CRACKANTHORPE, and others like him, who desire to bring about the end, should not only be explicit with regard to their choice of means, but should also be prepared for any indirect consequences which resort to these means may entail. It is possible, of course, that a husband and wife of a certain temperament may agree to practise abstinence; but the question is one which would seldom be discussed before marriage and which might easily lead, not only to grave unhappiness, but also to infidelity, in the event of subsequent disagreement with regard to it. The privileges of the husband, so far as the marriage bed is concerned, have perhaps never been questioned by any important authority; and the claims of the wife to payment of the conjugal debt, which have been explicitly upheld by many legislatures, notably by those of the Athenians and of the Jews, will also, we think, be upheld both by physiology and by the moral sense of the great majority of mankind. It is manifest that abstinence would destroy the apostolic antithesis between "to marry" and "to burn," by rendering it possible, or even customary, to do both; and we believe that the great majority of married folk would not materially limit the number of their children by any course short of complete abstinence. As for other devices, the procuring of abortion is both a criminal offence and a source of immediate danger to life, and gynæcologists can testify as to the likelihood of disease being set up by practices which aim, on the one hand, at stimulating a natural function into activity and, on the other, at preventing its physiological purposes from being attained.

---

[1] Cf. vol. ii., 1905, p. 216.

[2] Journal of the American Medical Sciences, January, 1907.

Mr. CRACKANTHORPE is eloquent upon the neglected state of the children of the poor, upon the ghastly mortality which prevails among them, and upon the diseased and crippled conditions which too often afflict the survivors. All these evils are undeniable; but they arise not so much from the birth of children as from the environment in which they are left by the permitted ignorance of their parents and by the defective sanitary administration of the State. Among children, as among all young animals, there must be a certain proportion of weakly individuals, not well calculated to survive, and the mortality of the first year of life must always be in excess of that of later periods, when the dangers besetting infancy have been escaped. But the excessive early mortality, which is justly regarded as a matter of national reproach, is largely an urban phenomenon, consequent upon remediable external conditions. During the ten years 1891–1900 the infantile mortality of England and Wales was 153 per 1000; but it ranged from 102 in Wiltshire and Dorsetshire to 160 in London and 179 in Lancashire; while out of the 153 for the whole country 44 deaths per 1000 were due to "wasting diseases" and 38 per 1000 of these occurred within three months of birth, while nearly half of them were attributed to debility or prematurity, the children possessing too feeble a vitality for the maintenance of an independent existence. It is well known that of children born prematurely between the end of the sixth and the middle of the ninth month more than two-thirds die before they are brought into the world, and less than one-fifth of the rest survive longer than a month. Moreover, in considering the effect of urban surroundings, it is well to remember that less than 60 years have elapsed since SIMON wrote of the City of London that "in houses containing all the sanitary evils which I have enumerated—undrained, and waterless, and unventilated—there are swarm of men and women who have yet to learn that human beings should dwell differently from cattle; swarms to whom personal cleanliness is utterly unknown; swarms by whom decency in their social relations is quite unconceived; women suffering travail in the midst of the males and females of three several families of fellow-lodgers in a single room; and, generally, people who are suffered to habituate themselves to the uttermost depths of physical obscenity and degradation." It is true that great changes for the better have since been wrought; but the effects of the conditions described by SIMON must endure much longer than the conditions themselves, and many generations must pass away before large sections of our urban populations can possess adequate conceptions of the requirements of health and decency. If Mr. CRACKANTHORPE were to carry his survey of Germany a little beyond the "unrest" which he attributes to a superabundant population, he might observe a people who are sufficiently educated to understand the value of scientific truth, industrial populations who are cleanly in their persons and apparel and comfortable and orderly in their homes, and parents who are successful in rearing and educating the children of whom he and those who think with him would deprive them, and who may often be the support and comfort of their declining years. It must not be forgotten that Mr. CRACKANTHORPE addresses his advice primarily to the more intelligent classes of the community, and that for them to follow it would be to diminish the number of their offspring both absolutely and relatively. Their comparative childlessness, like the celibacy of the clergy in the Middle Ages, would withdraw important intellectual and moral elements from the rising generation, and would afford increased room for a growth of tares by which the harvest of a better humanity would be choked. Among the English middle classes there has long been a sense of the value of the training which the conditions of a "large family" are commonly found to impart; and a very distinguished soldier, administrator, and public servant has lately told the readers of his "Memories" that he had the great advantage of growing up with ten elder brothers and sisters to teach him his place, and with eight younger to reconcile him to the inevitable supersession of seniors by their juniors. The lesson is, we think, at once a more moral and a more hopeful one than that which Mr. CRACKANTHORPE would inculcate.

them occupied during the forenoons and provide them with more material for compilation of their Service journal. Our large hospitals at home are all undermanned compared with the fleets and I believe the sole reason is that the hospitals come under a civil money grant which must be kept down.

The room for improvement is great and it is hoped that the favour shown to cricketers, footballers, actors, &c., in obtaining the best billets may soon cease. Lastly, when will something be done for the unfortunate sick-berth staff, the worst paid branch in the service, and who are entirely controlled by the executive and whose training is a farce?

I am, Sirs, yours faithfully,
July 13th. SURGEON, R.N.

*** It appears to us that in the case of sailors, marines, and civil employees of, or connected with, the Navy it would be manifestly part of the duty of a naval medical officer on full pay to attend any court of public inquiry at which his presence is required and make such professional investigations and examinations as may be necessary and we think that for this duty his pay and prospective pension is a retaining fee from the Service. In the case of an officer on half-pay we consider that the Admiralty has no moral or legal right to interfere in the matter. Naval medical officers on *full* pay are forbidden by the regulations to engage in private practice of any description, but in the event of any accident or sudden emergency occurring in the person of any civilian and in circumstances where the assistance of a private practitioner is not to be obtained, a naval medical officer, if summoned, would have a right to a professional fee. In such cases, which must be very rare, we cannot believe that the Admiralty has either the wish or the power to prevent him from receiving the fee due to him. In our opinion the Admiralty order to which our correspondent alludes is intended to refer only to duties connected with persons, whether civil or military, employed by the Admiralty in some one of its departments, ashore or afloat. We cannot believe that the naval medical officers who have done us the honour to read our columns believe that our prejudices are on the official side, and with some of the points mentioned by "Surgeon, R.N." we have already dealt. His whole letter, however, is an interesting and important document to which we shall later refer.—ED. L.

YANBO.

Situation and Character of the Town; it is the Port for Medina.—Proposal to put up here a Disinfecting Pavilion.—Difficulty in finding a Suitable Site.—A Floating Pavilion Suggested.—The Water-supply of the Town; its Precarious Character.

THE ports of Yanbo and El Wej are comparatively rarely visited by Europeans, particularly the latter. The former is, after Jeddah, the most important of the Hedjaz coast ports, and will probably always be so, since it occupies much the same relation to Medina as Jeddah does to Mecca. Its distance, however, from the corresponding Holy City of Islam is very much greater than in the case of Jeddah, the journey from Yanbo to Medina occupying some four or five days, whereas that from Jeddah to Mecca can be done on a fast camel in a single night, and rarely takes more than two days. The actual distances are approximately 130 miles and 45 miles respectively.

Yanbo is situated on the northern shore of a small bay. It is surrounded by desert and has an arid appearance, with practically no sign of vegetation. Behind, but at a distance of many miles, rises the fine range of mountains called Jebel-Radwa, portions of which are as high as 6000 feet above sea level. The town is not only much smaller but also less picturesque and attractive than Jeddah; it has a far less well-to-do appearance and few of the houses are adorned with those elaborately carved (and no doubt costly) wooden windows and balconies that abound in the larger port. At the moment of my visit there Yanbo was being rapidly invaded by some 10,000 pilgrims arriving by sea from Jeddah. The ship I travelled there by, though only of between 400 and 500 tons, had brought its contingent of over 500 pilgrims and other and larger ships were arriving daily.

Yanbo has the reputation of being a less civilised port than Jeddah; the pilgrims there, it was said (in Jeddah), became more fanatical and less amenable to restraint; the inhabitants were thought to be less accustomed to the sight of Europeans, and it was freely said that landing there, or at El Wej, might involve a certain risk. As a matter of fact, there is, perhaps, a certain small risk in any of these pilgrim ports, less though from the pilgrims than from the native Arabs. The murderous attack made on the foreign consuls in 1895 (when the British vice-consul was killed, and the British consul, Russian acting consul, and a member of the staff of the French consulate were seriously wounded, at a short distance outside Jeddah) is still fresh in the memory of those who have to reside in these ports. That attack was the work of native Arabs and bore no relation to the pilgrimage. So far as my limited experience may be allowed to count, there would seem to be little reason for apprehending danger from the Hajjis themselves, whether at Jeddah, Yanbo, or El Wej. At Yanbo the pilgrims were far more occupied in making arrangements for the start to Medina, in listening open-mouthed to the chanting recitals of itinerant preachers, or in taking a final sea-bath before their desert journey began than in paying any attention to the rare European visitor in their midst. Fig. 38 shows the first caravan of the season forming up in the market-place of Yanbo preparatory to starting for Medina.

The principal object of my visit to this port (in which I was not accompanied by the other members of the Commission) was the choice of a site for a disinfecting station which it is proposed to establish here. There is no doubt that such a station would be a great convenience both for pilgrims and for pilgrim ships. As stated in an earlier article, a considerable number of pilgrims from the north visit Medina before going to Mecca. If there is any measure of quarantine in force against their country of origin they are compelled to go to the Jeddah lazaret to accomplish it. When such measure is confined (as is frequently the case) to a simple "medical visit and disinfection" it bears rather hardly on both pilgrims and ships that they should have to go so far out of their way before pratique is granted them at Yanbo, and in many instances the pilgrims have taken the law into their own hands and under threats of violence have compelled the captain of their ship to go directly to Yanbo. On such occasions they are landed at Yanbo without undergoing any measures at all. It is to meet this unsatisfactory state of affairs that the Constantinople Board of Health has long desired to establish at Yanbo a disinfecting station, where the pilgrims would undergo a douche bath and the disinfection of their clothes and belongings in steam stoves.

The principal obstacle to carrying out this proposal has been the difficulty in finding a suitable site. One or two vacant spaces on the sea-shore within the town walls had been suggested but they were obviously unsuited. It would be impossible thoroughly to isolate the building from the rest of the town were it put up on one of these sites. Another suggestion was to utilise a reef near the middle of the bay which becomes an island at low tide and is known locally as Hobsa Island. At high tide this reef is some feet under water. Finally, and as offering at first sight quite the best position, the island of Abbasieh had been recommended. This is a typical coral island rather further from the town than Hobsa, long, narrow, and crescent-shaped. Its length was found to be 666 metres and its breadth from 25 to 88 metres. At its south-eastern end is the tomb of a certain Sheikh Abbas, from whom the island takes its name. His tomb has some local reputation as the shrine of a saint but it is not visited by the pilgrims. Close in two years and of the 10,363, 154 were fatal. These and other figures quoted in the report show that a real necessity exists for an extension and improvement in *our street ambulance service.* We have on many occasions called attention to the matter and the reports of meetings of the Metropolitan Street Ambulance Association, of which Mr. Reginald Harrison is the president, which have appeared in our columns, together with the correspondence relating to the subject, show that the medical profession has done its best to awaken the public interest in a matter which deeply concerns them. In a letter which Mr. Harrison addressed to us as recently as June 29th he *pointed out*—

[1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., and X. were published in THE LANCET of April 27th (p. 1188), May 4th (p. 1251), 11th (p. 1317), and 18th (p. 1389), June 1st (p. 1518), 8th (p. 1607), 22nd (p. 1741), and 29th (p. 1810), and July 6th (p. 51) and 13th (p. 114), 1907, respectively.

> (1) That the present position for dealing with such accidents and casualties in the streets is admitted to be inadequate and obsolete and that an unnecessary amount of mortality and physical suffering is thereby permitted to continue, (2) that though the better organisation of existing ambulance provision may to some extent improve matters a more extended system of first aid by the police or others who may undertake this duty, as well as improvements in signalling and in appliances and forms of ambulance are absolutely and urgently needed; (3) that *no service* for London can be regarded as efficient that does not include a proportion of rapid transit ambulances, motor or horse, capable of communicating immediately with accidents when authoritatively requisitioned by telephone or otherwise and containing, if required, necessaries for first aid attendance; in fact, in special circumstances and urgency reversing the order of things and bringing the hospital, so to speak, to the patient in the street.

The rapidly increasing traffic in our streets, especially motor traffic, makes it imperative that action should be taken with as little delay as possible. A Home Office inquiry relative to ambulances is now proceeding and every possible support should be given to the Metropolitan Street Ambulance Association in its endeavours to promote a more efficient service *for* the many thousands of accidents that occur annually in our streets. The secretary of this association is Dr. Arthur W. James, 69, Gloucester-terrace, Hyde Park, London, W.

THE "SIMPLIFIED EXPERT ALIENIST."

IN the second number of Vol. VIII. of the *Journal of Mental Pathology* (New York) one of the editorial articles deals with the partisan expert, an individual not uncommonly found in important murder trials. In this article we read that "the business of the simplified expert alienist" consists in simplifying the science of psychiatry. His definitions of mental derangements are strictly *sui generis* and cannot, therefore, be found in any of the writings of standard authors. "The field of activity of the 'simplified expert alienist' is in the court-room, where he may appear for the purpose of making it possible either for sane gentlemen *murderers* to escape the penalty of the law or for chronically insane gentlemen murderers to escape being landed in an asylum for insane criminals." The Penal Code (Section 20) for the State of New York reads as follows: "An act done by a person who is an idiot, imbecile, lunatic, or insane is not a crime. A person cannot be tried, sentenced to any punishment, or punished for a crime when he is in a state of idiocy, imbecility, lunacy, *or* insanity so as to be incapable of understanding the proceedings or making his defence." Now the "simplified expert alienist" so simplifies the nomenclature of mental diseases that such terms as idiocy, imbecility, paranoia, and other specific terms indicative of incurable mental diseases will be non-existent to him and when hard-pressed by overwhelming evidence for an opinion he commonly describes the insane gentleman's mental state prior to the murder somewhat as *follows*: "not perfectly healthy condition but not insane"; "unstable mentally but not insane"; "not lasting mental *state* but not insane"; "pathological suspect but not insane"; "on border line of insane instability and normal state *but* not insane." "All these and similar definitions may apply *to* the gentleman murderer's mental status *before* the commission of the murder. At the very moment of the murder the insane gentleman murderer may be found, however, to be suffering from a 'brain storm' or a '*brain explosion*' and is absolutely insane. But *after* the commission of the crime and at the time of the trial for murder the insane gentleman murderer is perfectly sane." The article concludes with the following remark: "We earnestly hope, therefore, for the sake of equity, public safety, and common decency that the present 'rule of evidence' may be changed in the near future and so perfected as to make it an act of justice to the public on the part of the people's attorney to kick out of court the 'simplified expert alienist' if he happens to appear therein in the rôle we have described and neatly to kick him into jail if he happens to deliberately attempt to aid and abet crime, criminality, and criminal acts."

FORCIBLE REDUCTION OF FRACTURE-DISLOCATION OF THE NECK.

A NUMBER of cases has now been recorded of recovery from fracture-dislocation of the cervical vertebræ but very few cases have been published of complete recovery after operation. In the *Journal of the American Medical Association* of June 8th Dr. A. A. Law has reported the following case. A boy, aged 16 years, was looking over the gate of a freight elevator with his chin over the edge. The elevator descended striking him on the back of the head. At the same time the gate ascended striking him in the region of the larynx. He was taken to hospital where Dr. Law saw him 20 minutes later. He was unconscious and *rigid* and made violent incoördinate movements. The limbs were markedly flexed and there were *complete* anæsthesia, exaggerated knee-jerks, ankle clonus, and paralysis of the sphincters. Respiration was diaphragmatic, shallow, and slow, and he was cyanotic. The pulse was 120 and thready. The head was forced back out of position and there was a dimple at the back of the neck over the spine of the third cervical vertebra. Palpation of the pharynx showed prominence of the body of the second cervical vertebra, which was dislocated forwards. The boy appeared to be *in extremis* and Dr. Law advised his parents that he should be given the chance of operation but would probably die on the table. He was placed on his back on the table, his head and shoulders extending over the edge. No anæsthetic was administered. While he was held by assistants by the shoulders and body Dr. Law, with one hand under his occiput and the other under his chin, made powerful traction on the head with no other result than to twice produce dislocation of the lower jaw which had to be reduced. Then with a folded towel over the teeth to protect his hand he made traction from this point and from the occiput. Meanwhile an assistant with his fingers in the pharynx pressed out the vertebræ. This was also unsuccessful. Finally, an assistant gripped Dr. Law's wrists and pulled with him. With all their strength they first extended and then flexed the head on the neck sharply and the vertebræ slipped *into place*. The symptoms instantaneously improved, showing that pressure on the cord had been *relieved*. *The* pulse and respiration became quieter, the incoördinate movements ceased, and sensibility returned. The patient was put to bed with the head of the bed raised and a 10 pounds extension weight on the head. Bromide of potassium was administered. Catheterism was performed for the first 24 hours, then urine was passed involuntarily. The temperature for the first ten days ranged from 100° to 102° F., while the pulse was 120. He remained unconscious for 12 days and was fed per rectum for four days. On the seventh day, extension being made on the head, the body was slipped over the edge of the bed and was held by assistants while Dr. Law applied a heavy plaster cast from the hips to the top of the head enveloping the patient completely save his face from the eyebrows to the mouth. This absolutely immobilised the head and shoulders. When the plaster set the extension was removed. He them occupied during the forenoons and provide them with more material for compilation of their Service journal. Our large hospitals at home are all undermanned compared with the fleets and I believe the sole reason is that the hospitals come under a civil money grant which must be kept down.

The room for improvement is great and it is hoped that the favour shown to cricketers, footballers, actors, &c., in obtaining the best billets may soon cease. Lastly, when will something be done for the unfortunate *sick-berth* staff, the worst paid branch in the service, and who are entirely controlled by the executive and whose training is a farce?

I am, Sirs, yours faithfully,

July 13th. SURGEON, R.N.

⁂ It appears to us that in the case of sailors, marines, and civil employees of, or connected with, the Navy it would be manifestly part of the duty of a naval medical officer on full pay to attend any court of public inquiry at which his presence is required and make such professional investigations and examinations as may be necessary and we think that for this duty his pay and prospective pension is a retaining fee from the Service. In the case of an officer on half-pay we consider that the Admiralty has no moral or legal right to interfere in the matter. Naval medical officers on full pay are forbidden by the regulations to engage in private practice of any description, but in the event of any accident or sudden emergency occurring in the person of any civilian and in circumstances where the assistance of a private practitioner is not to be obtained, a naval medical officer, if summoned, would have a right to a professional fee. In such cases, which must be very rare, we cannot believe that the Admiralty has either the wish or the power to prevent him from receiving the fee due to him. In our opinion the Admiralty order to which our correspondent alludes is intended to refer only to duties connected with persons, whether civil or military, employed by the Admiralty in some one of its departments, ashore or afloat. We cannot believe that the naval medical officers who have done us the honour to read our columns believe that our prejudices are on the official side, and with some of the points mentioned by "Surgeon, R.N." we have already dealt. His whole letter, however, is an interesting and important document to which we shall later refer.—ED. L.

YANBO.

Situation and Character of the Town; it is the Port for Medina.—Proposal to put up here a Disinfecting Pavilion.—Difficulty in finding a Suitable Site.—A Floating Pavilion Suggested.—The Water-supply of the Town; its Precarious Character.

THE ports of Yanbo and El Wej are comparatively rarely visited by Europeans, particularly the latter. The former is, after Jeddah, the most important of the Hedjaz coast ports, and will probably always be so, since it occupies much the same relation to Medina as Jeddah does to Mecca. Its distance, however, from the corresponding Holy City of Islam is very much greater than in the case of Jeddah, the journey from Yanbo to Medina occupying some four or five days, whereas that from Jeddah to Mecca can be done on a fast camel in a single night, and rarely takes more than two days. The actual distances are approximately 130 miles and 45 miles respectively.

Yanbo is situated on the northern shore of a small bay. It is surrounded by desert and has an arid appearance, with practically no sign of vegetation. Behind, but at a distance of many miles, rises the fine range of mountains called Jebel-Radwa, portions of which are as high as 6000 feet above sea level. The town is not only much smaller but also less picturesque and attractive than Jeddah; it has a far less well-to-do appearance and few of the houses are adorned with those elaborately carved (and no doubt costly) wooden windows and balconies that abound in the larger port. At the moment of my visit there Yanbo was being rapidly invaded by some 10,000 pilgrims arriving by sea from Jeddah. The ship I travelled there by, though only of between 400 and 500 tons, had brought its contingent of over 500 pilgrims and other and larger ships were arriving daily.

Yanbo has the reputation of being a less civilised port than Jeddah; the pilgrims there, it was said (in Jeddah), became more fanatical and less amenable to restraint; the inhabitants were thought to be less accustomed to the sight of Europeans, and it was freely said that landing there, or at El Wej, might involve a certain risk. As a matter of fact, there is, perhaps, a certain small risk in any of these pilgrim ports, less though from the pilgrims than from the native Arabs. The murderous attack made on the foreign consuls in 1895 (when the British vice-consul was killed, and the British consul, Russian acting consul, and a member of the staff of the French consulate were seriously wounded, at a short distance outside Jeddah) is still fresh in the memory of those who have to reside in these ports. That attack was the work of native Arabs and bore no relation to the pilgrimage. So far as my limited experience may be allowed to count, there would seem to be little reason for apprehending danger from the Hajjis themselves, whether at Jeddah, Yanbo, or El Wej. At Yanbo the pilgrims were far more occupied in making arrangements for the start to Medina, in listening open-mouthed to the chanting recitals of itinerant preachers, or in taking a final sea-bath before their desert journey began than in paying any attention to the rare European visitor in their midst. Fig. 38 shows the first caravan of the season forming up in the market-place of Yanbo preparatory to starting for Medina.

The principal object of my visit to this port (in which I was not accompanied by the other members of the Commission) was the choice of a site for a disinfecting station which it is proposed to establish here. There is no doubt that such a station would be a great convenience both for pilgrims and for pilgrim ships. As stated in an earlier article, a considerable number of pilgrims from the north visit Medina before going to Mecca. If there is any measure of quarantine in force against their country of origin they are compelled to go to the Jeddah lazaret to accomplish it. When such measure is confined (as is frequently the case) to a simple "medical visit and disinfection" it bears rather hardly on both pilgrims and ships that they should have to go so far out of their way before pratique is granted them at Yanbo, and in many instances the pilgrims have taken the law into their own hands and under threats of violence have compelled the captain of their ship to go directly to Yanbo. On such occasions they are landed at Yanbo without undergoing any measures at all. It is to meet this unsatisfactory state of affairs that the Constantinople Board of Health has long desired to establish at Yanbo a disinfecting station, where the pilgrims would undergo a douche bath and the disinfection of their clothes and belongings in steam stoves.

The principal obstacle to carrying out this proposal has been the difficulty in finding a suitable site. One or two vacant spaces on the sea-shore within the town walls had been suggested but they were obviously unsuited. It would be impossible thoroughly to isolate the building from the rest of the town were it put up on one of these sites. Another suggestion was to utilise a reef near the middle of the bay which becomes an island at low tide and is known locally as Hobsa Island. At high tide this reef is some feet under water. Finally, and as offering at first sight quite the best position, the island of Abbasieh had been recommended. This is a typical coral island rather further from the town than Hobsa, long, narrow, and crescent-shaped. Its length was found to be 666 metres and its breadth from 25 to 88 metres. At its south-eastern end is the tomb of a certain Sheikh Abbas, from whom the island takes its name. His tomb has some local reputation as the shrine of a saint but it is not visited by the pilgrims. [1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., and X. were published in THE LANCET of April 27th (p. 1188), May 4th (p. 1251), 11th (p. 1317), and 18th (p. 1389), June 1st (p. 1518), 8th (p. 1607), 22nd (p. 1741), and 29th (p. 1810), and July 6th (p. 51) and 13th (p. 114), 1907, respectively.

Reiche of Hamburg,[4] who states that a primary laryngeal case had not been recorded previously. The patient was a painter, aged 39 years, with a condition in the larynx very similar to that seen in the pharynx in Vincent's angina. The mucous membrane presented a thick, yellow, membranous infiltration in certain parts, but with very little irritation of the tissues around and with no enlargement of the lymphatic glands. The process spread for a few days and after separation of the pseudo-membrane a superficial ulceration of the mucous membrane was left which healed completely. There were not at any time any urgent symptoms although the vocal cords were involved, the chief clinical features being hoarseness and cough with abundant thin, watery expectoration. Fever was at first moderate; on one occasion the temperature rose to 39·8° C., but it fell to normal and remained there before the condition had ceased to spread. No diphtheria bacilli were discoverable either in the pseudo-membrane or in the expectoration, while the fusiform bacillus was present in great numbers. The spirilla usually found in association with it were not discovered in this case. Other interesting features were the protracted course of the disease in this instance and the occurrence of severe complications. At the height of the disease nephritis developed and later peripheral neuritis supervened, with paralysis of accommodation, weakness of the lower extremities, and some laryngeal paresis. The case is noteworthy not only because of the rarity of primary laryngeal implication but also because of the absence of spirilla and the marked similarity in the sequelæ to those of diphtheria, for which it would doubtless have been mistaken but for the careful bacteriological investigation.

A NEW ROMAN OCULIST SEAL.

Two Roman oculist seals have been discovered during 1905 and 1906 which bear somewhat fuller inscriptions than usual and which deserve notice in our columns. The first was found at Este, in Italy, and will not now be further referred to here because the discussion as to the correct translation of part of its text is still proceeding. The second seal comes from Reimersheim, near Mulhouse, and has been edited by Commandant Espérandieu who numbers it as 222 of the known seals,[1] the series of signets given by him in the Berlin Corpus of them in 1905 having terminated with number 219. The seal bears the name of two oculists, probably a proof of medical partnership, of which several instances have occurred previously. For instance, a seal preserved at Gotha belonged to T. C. Apollinaris and to Q. C. Quintilianus. The names upon the newly found specimen are Caius Julius Potentinus and Aurelius Amphio. Both names are new and nothing is known about their owners. The inscription graven respecting their favourite collyria runs as follows: "C. I. Potentini. Collyrium crocodem. Collyrium Stactum crocodes ad claritatem. Diamisus ad veteres cicatrices. Aureli Amphio Penicille ex ovo." Unfortunately this text does not afford any new scientific information, for all these collyria and terms for maladies have been exemplified upon signets found earlier. Crocodes was saffron and the herb is undoubtedly indicated by many, if not all, of the occurrences of the word upon oculist seals. But a French medical author has stated that often the saffron employed by the Roman oculist was not the vegetable product but what was entitled "Saffron of Mars," a name derived from its colour, and that it was really a hydrated oxide of iron. As metallic ingredients were especially popular with the seal owners this suggestion is possible. But, on the other hand, they certainly used the vegetable saffron as a remedy. Galen in his *Περὶ συνθέσεως* enumerates various collyria containing true saffron. The finest specimens of the plant for medical purposes, Celsus and Pliny assert, came from Sicily, though Dioscorides states that Sicilian saffron was not so powerful as that grown elsewhere. The great use made of it for medical purposes is proved by his devoting a special chapter to it. Marcellus and Aetius also allude to its use by oculists. Upon oculist seals it is stated to be efficacious against many forms of disease of the eyes, such as trachoma. Upon a seal found at Ratisbon it is styled *Crocodes regium tetrapharmacum.* It is mixed in collyria with misy, copper, and Judean balm. In this inscription it is united with stactum, or oil of myrrh, an ingredient presented upon more than 50 oculist seals. Here it is advised "ad claritatem," merely meaning to produce clearness of vision, just as some marvellous collyrium of green colour, styled Chloron, was by a certain G. Tittius Balbinus said to be useful "ad expurgationem et repletionem." The third collyrium, diamisus, is almost certainly sulphate of iron and the cicatrices which it cured were diseases of the cornea, but in some cases where the words "ad cicatrices" alone are used they may have been intended to promise that the ingredients would tend to cicatrise ulcerations and so to ease or to cure them, for Pliny vouches for a certain eye powder as producing such results. Penicillum was a species of fine sponge. Pliny in his "Natural History" speaks of it. It is nearly always on the seals qualified by the epithet "lene," or gentle. The mixing with the white of an egg has previously been found upon a seal associated with "penicillum lene," and it is advised to be used with incense, a decoction of rose leaves and nard, upon the oculist seals.

PNEUMATURIA.

THOUGH pneumaturia has been described so long ago as 1671 by Raciborsky its literature is still scanty and its investigation far from complete. In the *Boston Medical and Surgical Journal* of June 13th Dr. A. E. Taussig reported the following case. A coloured woman, aged 34 years, had carcinoma of the cervix uteri which involved the vagina and left arametrium. Panhysterectomy and removal of the parametrial connective tissue were performed. As usual after such operations she was unable to micturate and catheterisation was necessary. The urine was normal. On the sixth day after operation it became cloudy and on the following day when the catheter was introduced the urine was expelled with bubbles of odourless gas. First, a varying quantity of turbid urine was expelled, then puffs of gas interrupted its flow, and finally a quantity of frothy urine was passed. The pneumaturia continued for ten days, during the last few of which the power of micturition was regained. Under boric acid irrigation the cystitis gradually ceased, but two months later it recurred and continued until death from recurrence of the cancer. At the necropsy the bladder showed only the characters of chronic cystitis and no communication with the rectum was found. The urine during the period of pneumaturia was faintly acid. It contained pus but no sugar. Cultures of the urine on agar, aerobic and anaerobic, showed only one microbe, a thick bacillus with rounded ends, often so short as to resemble a micrococcus. It was slightly motile, produced no spores, and did not retain Gram's stain. It grew readily on all ordinary media. In neutral red glucose agar and in nutrient agar and gelatine gas was produced. But attempts to imitate the intravesical formation of gas by inoculating normal urine or the patient's urine failed—an experience which is similar to that of other observers. Attempts to analyse the gas were only partly successful; the presence of carbonic acid was ascertained. There are two forms of pneumaturia. One is due to the passage of gas from the rectum into the bladder

[4] Münchener Medicinische Wochenschrift, 1907, No. 17.

[1] Bulletin de la Société Nationale des Antiquaires de France, 1905, p. 152.

The disinfecting pavilion, whether constructed on dry land or on a floating barge, will follow more or less closely Plan VI., which is reproduced here in miniature. Two pavilions on the same plan have already been put up, one at Jaffa and the other at Rhodes, and those which it is intended to build at Trebizond, Salonica, and Valona will be on similar, if not identical, lines. The plan explains itself; the left wing contains waiting room, undressing room, bath room, and dressing room for men; the right wing has similar, but smaller, rooms for women. In the middle are a room for sorting the clothes and effects of the pilgrims, two other rooms, "contaminated" and "clean," with the steam stove fixed in the party wall dividing them, and a room where chemical disinfection can be carried out. In the last will be constructed three large cement-lined troughs to hold the disinfecting solutions. The cost of such a pavilion varies in different localities; that at Jaffa cost rather more than £1000 sterling; the estimate for a similar pavilion at Yanbo (on land) amounts to nearly £1300.

Yanbo is said to contain about 5000 inhabitants; for the four hottest months of the year the great majority of the population migrate from the port, which is known locally as Yanbo-el-Bahr ("Yanbo by the Sea") to another town, some six hours distant, known as Yanbo-el-Nakhl ("Yanbo of the Dates"), where, as its name implies, dates are the principal product. The latter town is said to have an excellent supply of water, but at the former water is scarce and dear. Rain falls but rarely; once a year, perhaps, there may be a fall, but sometimes there is complete drought for two or three years. In the intervals the town is dependent for its supply upon the cisterns outside the walls, which in every way resemble those at Jeddah, described in an earlier article. Not infrequently there is a veritable water famine and the price of water becomes excessively high. In 1900, for example, at one moment the garrison of 120 soldiers was paying three Turkish pounds (£2 14*s.*) a day for its water. Some water is also brought into the town on camel back from Oués, some six hours distant; but the Bedouins, it is said, not infrequently attack the water-carriers and capture their asses and camels. Altogether, the conditions under which Yanbo obtains its drinking water can scarcely be regarded as ideal and it may be hoped that the declared intention of the Turkish Government to put up here, as at Jeddah, a distilling apparatus will in truth be carried out.

Yanbo has a kaimakam, or Turkish governor, and representatives of the Ottoman Public Debt Administration and of the Tobacco Régie reside here. There is also a representative of the Grand Sherif of Mecca, known as the Emir-i-Djuheiné, who has considerable powers; he is chief of the tribe to which he belongs and, as claiming descent from the Prophet, is much respected by the Bedouins.

(*To be continued.*)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Dental Association.

THE annual meeting of the North Midland branch of the British Dental Association has just been held at the University of Manchester. On July 12th Dr. Hopkinson, the Vice-Chancellor, gave an address of welcome to the members and referred to the closer connexion between the dental profession and the University that had grown up in recent years. There are now a large number of students preparing for the dental profession, and the University has instituted a degree and diploma which have received full recognition. The Vice-Chancellor said that "they wished to make the degree a work not only of practical proficiency but also of a good general scientific education." It seems that the dentists are to be furnished with a subject for controversy, for the retiring President, Mr. O. Rippon, said he regretted that a code of fundamental principles on the subject of provident dental aid had not been agreed upon and that in the meantime a provident institution had already been established in the south. Those who are aware of the troubles and the disputations over the provident medical dispensaries in Manchester will agree that the dental profession should carefully consider the matter and should take up a definite and well-thought-out position. The subject of attention to the teeth of school children was considered by both the retiring President and the new President, Mr. G. O. Whittaker. The former thought that the education authorities were now more fully alive than they were to the need of such attention and were ready to move with the association. In his address Mr. Whittaker pointed out the amount of physical disability caused by neglect of the teeth and the national loss which resulted. He thought that the mere examination of the teeth by a qualified man would do good. The dentist could report to the parents and where there was a dental hospital the remedy was within the reach of poor people. Absence from school through toothache means loss of grants and he thought that the cost of dental supervision in the public elementary schools would be largely provided by increased grants. In cotton mills, too, much loss to employers and employed is caused by "broken time" through "face-ache." He made a suggestion that no doubt will be welcomed by the Manchester and Salford Sanitary Association—namely, that it was desirable that a dentist should be appointed on the committee. However, the dentists and not the Sanitary Association are responsible for this deficiency, as the former have never, so far as I am aware, shown any wish to join the committee of the association.

Killed by Her Hairpins.

An unusual cause of death was inquired into last week by the Blackburn coroner. A woman, 57 years of age, fell backwards downstairs and her head struck a door at the bottom. Several of her hairpins were driven "right into her skull." She died two hours afterwards. No other injuries were recorded. Many of the long, strong pins, with points like needles, with which women fasten on their hats are well known as dangerous weapons, but presumably in this instance the fatal injury was caused by the smaller variety, generally held to be comparatively harmless.

Stockport Infirmary and the Coroner.

It is always to be regretted when adverse comments, even if they be undeserved, are made at a coroner's inquest on the treatment of hospital cases. It is acknowledged that, though an error in judgment is possible, those in charge of the sick and injured are painstaking and humane. Yet whenever an opportunity occurs to question the treatment adopted there seems a tendency to take the most unfavourable view. This is the more to be regretted, because it fosters the idea entertained by the more ignorant of the public, or a large section of them, that hospitals are "places for doctors," as it is often put, "to try their experience on you." An inquest was held on July 9th at Stockport on a man who was at his work in a brickyard when about half a ton of clay fell on him, covering the whole of his body with the exception of the head. He was released and taken to the infirmary and after being treated there was sent home. He was said to have been in great pain while at the infirmary, but the medical officer did not consider him bad enough to be detained. The coroner said that "he should like to have heard what the medical man at the infirmary had to say as to why the man had not been detained there. ...... There was sufficient cause to call for an explanation from the medical officer at the infirmary, and he hoped that such explanation would be forthcoming." The verdict returned was "Accidental death," and the jury regretted that the man was not detained as an in-patient. The tone of the coroner's remarks was not pleasing to the infirmary board, which met the day after, and the chairman said that the house surgeon's version was that the patient was examined by himself and Dr. Milner and that there was little reason why he should have been taken in. The members of the medical staff who were present expressed entire confidence in the senior house surgeon but said that if they had known the history of the case as they did then they would have detained the patient. It is, of course, quite possible that the case would have ended fatally if the man had been detained, but the moral to which it points seems to be that any case at all doubtful should be kept in until its character is fully known.

Weather and Vagrants.

A curious fact testifying to the influence of the weather on various callings came out at the Bury board of guardians last week. Attention was drawn to the fact that the number of vagrants in the workhouse during the past few weeks was 50 per cent. higher than in the corresponding period of last year. The chairman said "this was remarkable considering the good trade that prevailed in the district." One member suggested that the bad weather affected outdoor and it seems probable that it is the commonest organism giving rise to pyelitis. The solutions employed for washing out the pelvis were nitrate of silver (1 in 6000 and 1 in 5000) and argyrol. Of the six cases two were failures and nephrectomy was the only possible method of cure; the four other cases were satisfactory, three recovering completely. In one case both pelves were affected but the ureteral catheter had to be passed only four times and perfect recovery followed. It is certain that this patient suffered much less discomfort than if the pelvis had been opened by a lumbar incision. In this case no gonococci were found and the more rapid recovery may possibly be connected with this fact.

EPIDEMIC CEREBRO-SPINAL FEVER.

THE fact of the diminished prevalence of epidemic cerebro-spinal fever seems now to be well established. In Scotland during the week ended July 13th there were 6 deaths from this cause registered in Glasgow, 4 in Edinburgh, 2 in Leith, 1 in Dundee, and 1 in Paisley. In Glasgow the weekly report issued on July 12th showed that there were at that time 53 cases under treatment. In Belfast during the week ended July 6th there were 10 deaths registered as being due to this cause.

AN INTERESTING CASE OF GASEOUS EMBOLISM.

A REMARKABLY accurate and complete translation of an interesting case of gaseous embolism reported by Lieutenant N. Low in the *Journal of the Royal Army Medical Corps* for April last appears in the *Archives de Médecine Navale* for June. The name of the translator is not supplied but he is to be congratulated on his admirable rendering of a language differing in so many respects from his own vernacular. Without being given word for word the precise meaning of the original is conveyed in elegant and idiomatic French. We have been able to detect one slight mistake only. Referring to the body weight lost by the patient the translator in a note says that a stone is equal to 3·628 kilogrammes, and adds that it is the unity employed in weighing meat. It is no wonder that he was led into error. The number of different "stones" used in this country must be most perplexing to a foreigner accustomed to the simplicity of the metric system. It is true that the only legal weight bearing the name is the British imperial stone of 14 pounds, but in various parts of the kingdom stones of other values are in use, as a stone of 24 pounds for wool, 22 pounds for hay, 16 pounds for cheese, 32 pounds for hemp, 5 pounds for glass, 8 pounds for butcher's meat, and in Scotland 7 pounds for oatmeal.

THE DEATH OF DR. DUPRÉ.

ANALYTICAL chemistry loses one of the best of its exponents in the death of Dr. August Dupré, which took place on Monday, July 15th, at Sutton, Surrey. His name came prominently before the public in connexion with the Fenian outrages in the early "eighties" when, as chemical adviser to the Explosives Department of the Home Office, he investigated the explosives and infernal machines employed in the Fenian propaganda. He was also engaged on some important medico-legal cases and was associated with Dr. (now Sir) Thomas Stevenson in the task of detecting poisons which had been criminally administered. Dr. Dupré was an authority on water analysis and did much to render exact the analytical processes concerned. Perhaps his most important investigation in this connexion was that relating to the amount and estimation of oxygen dissolved in waters. He presented a report on this subject to the Medical Department of the Local Government Board in 1884, and one interesting conclusion was that in the vast majority of cases the consumption of oxygen from the dissolved air of a natural water is due to growing organisms and that in the complete absence of such organisms little or no oxygen would be consumed. Dr. Dupré added considerably also to our knowledge of the chemistry of wines and spirits and was the first to propose a rational method for the estimation of the higher alcohols, or, as they were then called, fusel oils, in spirits. He was at one time public analyst for Westminster and was lecturer on chemistry for over 30 years at the Westminster Hospital Medical School.

THE CALCUTTA CORPORATION AND PUBLIC HEALTH.

THE Calcutta Corporation is engaged in organising its health department, which is not a new departure for seldom does a year pass without some scheme being broached It is to be hoped that the one now adopted will prove satisfactory, for continual change, or the threat of change, does not conduce to efficiency or to enthusiasm on the part of the department concerned; nor does too frequent criticism of a hostile character help a department to do its best. Praise, even when it is seldom and when well deserved, has often a more powerful effect. Good pay and fixity of tenure, two important conditions which the municipality is rather inclined to ignore, will always secure good men, and with these granted it is pretty certain that the most serious difficulties confronting the health administration would disappear. Into the merits of this new organisation scheme we cannot enter, because from the papers before us it is not very clear whether it is merely an amalgamation of the hitherto separate plague department with the health department under the health officer or whether it is the abolition of the plague department and the transference of these duties to the health department. If it is the latter we think that the corporation is making a great mistake. The city of Calcutta is not only the capital of India but it is also the great commercial centre of that part of India. It is of the highest importance, therefore, that plague should be kept under control, for if this disease by any relaxation of effort should gain a further hold on Calcutta and become epidemic the loss in lives and in money would be great. The amount of money expended annually in maintaining a plague department is microscopic compared to the losses which would be incurred in a week's time in consequence of an epidemic in such a prosperous city as Calcutta.

THE SECOND INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.

THE Second International Congress on School Hygiene will be held at the University of London from August 5th to 10th under the presidency of Sir Lauder Brunton. We have already expressed the hope that the results of its labours will be a more general recognition on the part of the public of the fact that the mental and physical condition of children must be taken into consideration in connexion with any scheme of primary education. Science has already recognised the folly of educating children at the expense of their bodily and mental health, but a strong public opinion is needed before any legislation can be expected. The public are, we believe, beginning to see the necessity for some alteration of the present system of education and the Government has displayed great interest in the matter, even though it is possible to suggest that not much has been done as yet. On July 15th, in answer to a series of questions in the House of Commons, Mr. McKenna said that the Board of Education was greatly interested in the approaching Congress on School Hygiene and had intimated its intention of sending three of its officers to attend the Congress. He hoped, he said, to derive much information from its proceedings and he had done his best to facilitate its deliberations

Funeral of Sir William T. Gairdner.

On July 2nd the remains of Sir William T. Gairdner were interred in the family burying-ground at the Western Necropolis, Glasgow. It was peculiarly fitting that the principal ceremony should take place in the Bute Hall of the University of Glasgow, where for nearly 40 years he filled the chair of practice of medicine. Among those present were the members of the senate and University Court, representatives from the corporation of Glasgow, the general council of the University, the Faculty of Physicians and Surgeons, Glasgow, and the University of Edinburgh.

The Trial of Purves for Shooting Dr. R. Carswell.

The last stage of the "Purves insanity" episode took place last week when Purves was sentenced to seven years' penal servitude. It will be recollected that nearly three years ago Purves was certified insane by Dr. Carswell and Dr. Marion Gilchrist. On being liberated from the asylum he brought an action of damages for £10,000 against each of them, but the case was decided against him in the Court of Session. Two months ago he shot at and wounded Dr. Carswell with a revolver in one of the public streets of Glasgow, his avowed object being not to kill but to bring Dr. Carswell into the witness-box. At the trial the course of events was somewhat unusual, the Advocate Depute for the prosecution trying to prove the prisoner insane; while, on the other hand, counsel for the defence, acting under the prisoner's instructions, maintained his sanity. Medical experts were called on both sides, the evidence being very conflicting, but eventually the jury decided in favour of his sanity, with the result that a sentence of seven years' penal servitude was conferred. The whole incident from beginning to end has served to demonstrate the unsatisfactory position of medical men with reference to the granting of certificates of insanity.

Enteric Fever at Peterhead.

Several meetings of the town council of Peterhead have been held to consider the situation caused by the large number of cases of enteric fever, and at a recent meeting Provost Leask gave a summary of what had been done since the outbreak of the fever. From this it appears that on June 8th an emergency meeting of the public health committee was held at the request of the medical officer of health who reported that a serious outbreak of enteric fever had taken place in the burgh. The sanitary inspector at the same time submitted a report of analysis of the water-supply from (1) Forchill; (2) Grange; (3) chamber near Downiehills; (4) Downiehills Burn; (5) Cairncatta supply; and (6) Wellington supply. In consequence of these reports the inspector was instructed to make further examinations of these sources of supply. The inspector at the same time reported that the sources from the Downiehills Burn and chamber had been cut off. The committee again met on June 12th, when the result of the sanitary inspector's further analyses was intimated and in consequence a notice was sent to all the inhabitants warning them to boil all water used for drinking or domestic purposes. At a meeting of the water committee held on June 15th it was resolved to run off the water in the Grange reservoir and to give the latter a thorough clean out. The public health committee again met on June 26th, when it was reported that the water from the Forchill reservoir, though improved, was still of bad quality. On June 28th the public health committee again met for the purpose of providing additional accommodation required for the increased number of cases. It was decided, if found necessary, to make arrangements for a temporary building in the hospital grounds and to endeavour to secure accommodation in the Strichen hospital. At a meeting of the town council on July 1st the medical officer of health was authorised to procure an assistant, and among other things it was arranged that the fish-curers should be asked to use salt water for cleaning their fish and that the police should be asked to direct their attention to any waste of water. On July 5th a special meeting of the town council was held for the purpose of meeting Dr. F. Dittmar, medical inspector of the Local Government Board, and of considering the measures to be adopted in connexion with the outbreak of fever. At this meeting a telegram was read from the Local Government Board stating that both the Board's medical inspectors and the burgh medical officer of health were prepared to certify that one of the reservoirs was typhoid infected—this being the Forchill reservoir from which no water was at present being taken. Analyses of water from various sources were submitted. Dr. Dittmar was then called in and heard very fully regarding the conditions of the water-supply and the methods to be adopted to combat the epidemic. Thereafter the position of matters was fully discussed and it was resolved:—

1. To close the Forchill reservoir until further consideration by the town council, the reservoir not again to be used for domestic purposes.
2. To endeavour to go on with the supply from the Wellington and Cairncatta sources; if found insufficient the council to arrange for an intermittent supply.
3. To issue a further warning to consumers to boil water before drinking or using for domestic purposes.
4. To boil water at several parts of the town for public uses.
5. To warn the public against using the water from the Cairntrodlie, Blackhouse, and Washinghouse Green wells without first boiling it for at least ten minutes.

The epidemic shows signs of abating during the last few days, to judge from the number of notifications. So far 170 cases have been notified, but a large number of these have been very slight. The temporary hospital is now ready for occupancy and the most urgent cases are being removed there. 42 cases are already in hospital and all are making good progress. Several cases have been removed to Strichen Hospital. About a dozen deaths have so far been attributed to the malady. The fishing community has escaped almost entirely so far from the fever. Surface water is used at Peterhead to augment the supply when it appears likely to fall short of the demand and the recent heavy rains washing well-manured fields are probably responsible for the epidemic. I understand that the Admiralty and Prison Commissioners have very generously consented to allow the Peterhead town council to take the surplus from their water-supply. It is expected that this supply will run from 30,000 to 40,000 gallons per day. The work of connecting the supply with the pipes of the town supply has almost been completed. The water is of undoubted purity as it goes through a process of filtration. This additional supply enables the town council to cut off some further doubtful supplies.

July 16th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland: Royal Visit to Dublin.

THE address from the Royal College of Surgeons in Ireland (represented by Sir Henry R. Swanzy, Mr. John Lentaigne, Sir Charles A. Cameron, Sir Arthur Chance, and Mr. G. F. Blake, Registrar) was the following:—

> We, the President, Vice-President, and Council of the Royal College of Surgeons in Ireland, desire to avail ourselves of the presence of your Majesties in Dublin to offer the assurance of our allegiance to your Majesties and our respectful and loyal welcome on the occasion of your gracious visit to Ireland. It is the object of our Royal College to provide highly qualified surgeons who may serve their country in the Naval or Military Services, as well as those others who will devote their lives to the care of the sick in the civil community. Knowing the deep interest your Majesties take in all that concerns the welfare of your subjects and the progress of surgical science, we feel confident that our Royal College may rely on your Majesties' favour in our continued efforts to secure the efficiency of those who seek our diplomas.
> Signed on behalf of the Council.
>
> HENRY R. SWANZY, President.
> JOHN LENTAIGNE, Vice-President.
> CHARLES A. CAMERON, Secretary.

His Majesty gave the following general reply to all the addresses and handed a copy of it to each deputation:—

> GENTLEMEN,—I thank you for the hearty greetings and cordial welcome which you have tendered to the Queen and myself, and I accept with sincere gratification your loyal assurances of devotion to my Throne and person.
>
> I am pleased to hear of your success in your various spheres of public duty, and I trust that a blessing may continually follow your labours for the prosperity of the country and the welfare of the people.
>
> I regret that time does not admit of an individual acknowledgment of your addresses, but I ask you to accept from the Queen and from myself an assurance of our gratification at your kindly reception of us and of our hearty sympathy with you in your efforts for the good of the various communities which you represent.

Health of Belfast.

It was reported to the public health committee at the weekly meeting on July 11th that for the week ending July 6th there had been six cases of cerebro-spinal meningitis, as against 11 for the previous week. Since the last meeting of the committee (July 4th) only three cases were notified, as against five in the previous week, and for the week ended Saturday, July 6th, five deaths were owing to the number of aged women enrolled under the "already in practice" clause,[3] be for some time very considerable. The number of midwives struck off the roll during the years 1905–06 was 41.

(b) *The number or proportion of untrained midwives on the roll*—i.e., of women admitted to the roll within the first two years after the passing of the Act in virtue of their having been in *bonâ fide* practice as midwives for the 12 months preceding the passing of the Act. The last edition of the Midwives Roll which was published in July, 1906, gives the names of 23,278 midwives; of these 12,356 were placed on the roll in virtue of having been already in practice before the Act was passed. If, to the number remaining, is added the number of women who have since been enrolled, in virtue of having passed the examinations held by the Central Midwives Board in June, August, October, and December, 1906, and in February, 1907—viz., 1282—the number thus obtained will represent (approximately) the total number of trained women now on the roll.

The following table showing in respect of certain counties and county boroughs, (1) the population, (2) the number of practising midwives, and (3) the number of trained midwives will convey some idea of the enormous proportion of untrained women at present practising:—

County, or Borough.	Population.	Number of practising midwives.	Number of trained midwives.
Cardiff	183,823	108	22
Cheshire	629,217	435	85
Cambridgeshire	120,150	66	24
Derbyshire	524,620	400	51
Glamorganshire	467,954	573	36
Gloucestershire	321,442	269	84
Monmouthshire	230,806	197	11
Newport	75,585	38	13
Plymouth	120,083	38	7
Lancashire	1,774,467	991	204
East Riding	148,237	26	4
North Riding	250,712	60	11
West Riding	1,473,366	833	134
Shropshire	239,783	342	72
Walsall	94,000	47	—
Warrington	69,153	29	12
Wolverhampton	100,857	45	9
Worcestershire	385,610	407	76

In addition to the untrained midwives on the roll there is a considerable number of women practising as midwives without being on the roll. Thus, for example, in Berkshire there are about 90 such women practising, and at South Shields (according to the medical officer of health) from 30 to 40.

(c) *The average rate of payment of midwives in private practice, especially in rural districts, and the average number of cases which they attend annually.*—It has been difficult to obtain accurate statistics as to the average rate of payment of midwives, but some trustworthy information has been obtained with regard to certain districts; thus, at East Hoathly, in Sussex, the fee is 7*s*. 6*d*.; at Chipstead, in Surrey, the fee is 10*s*. 6*d*. (a bottle of brandy being also expected); in an agricultural district near Hythe, in Kent, where the wages range from 16*s*. to 20*s*. a week, the old midwives received a fee of 7*s*. 6*d*. and at least one bottle of spirits, to be shared with the patient; and in an agricultural and mining district near Radstock, in Somersetshire (wages being from 14*s*. to 24*s*.), the old fee was 3*s*. 6*d*. for the confinement alone and 5*s*. if the baby was washed during the ensuing week, five or six shillings' worth of spirits being also invariably expected. In these two last-named districts of Kent and Somersetshire the midwife did not cook, wash, or assist in housework. "It would," says Miss Alice Gregory (to whom the committee is indebted for most of the above information), "probably be a fairly accurate statement to say that in rural districts ...... the cost of a midwife's attendance has averaged 10*s*., although this amount is rarely paid entirely in money. In better-class neighbourhoods of London, as West Kensington and Plumstead, midwives charge a minimum fee of 10*s*., but in London generally 10*s*. would be more correctly described as the average fee, and in districts near training schools this fee would be unobtainable ...." In Bath the midwife's fee varies from 5*s*. to 15*s*., attendance on mother and child for ten days being included; but the usual charge is 7*s*. 6*d*. In Manchester the average fee is 10*s*. 6*d*.

The average number of cases attended annually is even more difficult to compute. In a town, where the cases are near together, 200 is said to be a not very unusual number for a trained and active midwife, but the average is considerably below that number. For example, of 212 midwives in London 22 attended more than 300 cases in the year, ten attended between 250 and 300, 12 between 200 and 250, 22 between 150 and 200, 32 between 100 and 150, and the remaining 94 under 100.[4] In Bath one midwife attended about 90 cases, two district nurses attended about 90 between them, 96 cases were fairly evenly distributed amongst three midwives, and 102 were unevenly distributed amongst 24 midwives.

On the question of the average remuneration of midwives valuable information has been furnished by Miss Amy Hughes, General Superintendent of the Queen Victoria's Jubilee Institute for Nurses, which, though not strictly relevant to the inquiry as to the rate of remuneration *in private practice*, nevertheless has an important bearing on the general question, especially in view of the fact that the Queen Victoria's Jubilee Institute is the largest employer of midwives in this country.[5] "The midwives working for the Institute in country districts are not paid by the case," says Miss Hughes, "but are paid a salary. The salaries of the Queen's nurses begin at £30 a year and 'all found'; the salaries of the village nurses range from £45 to £70, and they 'find themselves.' The payment of the patients to the associations varies from 2*s*. 6*d*. to 15*s*. (in Sussex from 1*s*. 6*d*. to 7*s*. 6*d*.; in Yorkshire, from 5*s*. to 30*s*., and in Herefordshire from 5*s*. to 21*s*.)."

In rural districts generally the number of trained midwives following the occupation of midwife alone is very small. In Miss Gregory's own practice in Somersetshire the largest number that she attended in any one year was 150 and Miss Gregory is of opinion that in any similar district—that is, in a district extending three or four miles from the midwife's house in every direction—that is about as large a number as can be satisfactorily attended. In East Sussex only 20 midwives attended more than 20 cases each per annum. Of these 20 midwives, 14, of whom 12 were in private practice, practised in urban districts and six, of whom three were in private practice, in rural. Of the 12 who were in private practice in urban districts one attended 76 cases, one 60 cases, one 52 cases, and one 50 cases, while the remaining eight attended 246 cases amongst them, an average of 32. The three who were in private practice in rural districts attended exactly 24 cases each. The average number of cases attended in small urban and rural districts by each practising midwife is 18.

(d) *The proportion of country districts where it would, and where it would not, be possible for a midwife following no other occupation to earn a livelihood.*—In reference to this question of the possibility of earning a livelihood Miss Hughes says: "We have no districts [in connexion with the Queen Victoria's Jubilee Institute] that could support a midwife who did no other work and it is our experience that rural midwifery can be quite well combined with 'non-infectious' nursing. In fact, this seems to be the best solution to the rural problem." In a supplementary note to the very valuable statistics which he has prepared and of which a summary will be found incorporated in this report Mr. Foulerton makes the following observations: "This inquiry having been made mainly with the view of ascertaining the means of subsistence available, under the existing condition of things, for properly qualified midwives, we may call attention to the following facts. In the first place the supply of certified midwives is, at first sight and as judged merely by the actual number of births, very much in excess of that required by the demand for their services. The number of certified midwives whose names appear in the last edition of general from the Montevidean War Office, adding, 'Such distinctions would only oppress me." Looking simply to the triumph of the cause he had at heart—the good of his fellow man—he was quite indifferent to the "glory of victory," so long as the victory was gained. Such self-abnegation has its lessons, as I have, said, not only in the military sphere, but even in those of science, of fine art, and of literature. The jealousies among the votaries of these pursuits—jealousies not confined to his compatriots, among whom, it is true, they are all too manifest—are in strong contrast to Garibaldi's noble freedom from the *amour propre*, the self-assertion, in which these jealousies have their source. Science, nature study, in which the attainment of truth is the one real object to aim at, are prolific in examples of the ignoble jealousies indicated, claims to priority in this or that "discovery" or even "*observation*" being loudly advanced and as loudly met by counterclaims, till the controversy from a personal achieves an international significance. Some 30 years ago persistent attempts were made to assert for Cesalpino a "priority" over Harvey in the discovery of the circulation—attempts which did not survive the demonstration by Dr. George Johnson of King's College that the discovery, gradually led up to, belonged ultimately to the English anatomist. Again, the counter-claims of Adams and Leverrier to the discovery of the planet Neptune—claims, be it said, which were advanced not by the discoverers themselves but by eager *chauvinistes* of British or French nationality—have ceased to be heard now that it is recognised that both astronomers, well-matched in scientific aptitude, and working on the same lines, were bound about the same time to reach the same *terminus*. Such coincidences tend to become more and more frequent as the interdependency of work in the same field becomes more and more real and effective. "Nothing in this world is single," says the poet, "all things by a law divine, in one another's being mingle," till claims to "originality" or "priority" will appear not only ignobly egotistic but in every sense unphilosophic.

---

[3] For example, out of 348 midwives in Shropshire 99 are between 60 and 70 years of age and 28 are over 70.

[4] There are 490 midwives in London, but of these only 212 sent in lists of births sufficiently regularly to be available for this purpose.

[5] In 1906, 11,502 midwifery and monthly cases were attended by 429 certified midwives connected with the Institute.

The Treatment of Pulmonary Tuberculosis: a New Method.

Dr. Carlo Forlanini, professor of clinical medicine in the University of Pavia, has proposed a treatment for pulmonary tuberculosis which seems to have other merits than its undoubted novelty. Cases of real arrest of the slow destruction of the lung, while not so rare as is supposed, he would ascribe not to the medical treatment but to a fortunate resumption of strength on the patient's part, sufficient to react against the disease. In two lectures recently delivered before a professional audience at Milan—lectures embodying the results of 20 years' study and experience, clinical and experimental—he gave a pathological history of the disease in its inception and progress, and endeavoured to show that the characteristic cavities (*vomicæ*) are the result of other causes than those consequent on the bacillus of Koch—may, in fact, be the outcome of "all those micro-organisms which can produce catarrh in the interior of the pulmonary alveoli." This catarrh, he proceeds to show, consisting of a mass of dead cellules, of degenerate elements, and of different species of micro-organisms, fills the pulmonary alveolus in the act of respiration under pressure of the air which seeks to enter the said alveolus, and thus, though relieved by expectoration, interposes a serious obstacle to the sanguineous circulation. Thanks to this obstacle and to the consequent denutrition of the tissues the walls of the alveolus become enfeebled until they are destroyed and give place to a primary small cavity which by the same mechanical process enlarges into a cavity or cavities still greater. The conditions under which a cavity is formed consist in the pulmonary function—that is, in the mobility of the lung itself. Further, he contends that while a lung slightly diseased from tubercle gets well if it performs its function duly a lung in process of destruction cannot get well unless complete immobility be induced. A clinical case of frequent occurrence illustrates this law. When around a tuberculous lung there is formed a copious gathering of liquid (as happens in pleuritis), so that the lung remains shrivelled and immobile, and when this liquid continues for a sufficient time the affected lung loses its functional power but it gets well. Now (says Professor Forlanini) the method of cure I propose is precisely this—to introduce into the thoracic cavity not a liquid, because the operation would be difficult, even dangerous, but a gas, that gas which is at once inert and innocuous, azote. This, we know, is prepared by a very familiar chemical reaction in a glass apparatus and is introduced into the thoracic cavity by a fine needle. The pressure of the gas is so regulated be a little higher than the pressure of the atmosphere, to overcome the tendency of the lung to distend. B means when the thoracic cavity is full of gas the lu pushed up, shrivelled, and reduced to an inert mass, preventing the disease from pursuing its fatal course. walls of the great cavities come in contact with other; all that material of the disintegration of tissues in which the most varied microbic forms germinating is squeezed out; the connective tissue constitutes the elastic support (*sostegno*) of the lung get ascendancy, and so the entire diseased part becomes a of cicatrices. We are not to suppose, however, tha this happens after a first introduction of the gas. pleura has great absorbent power; the azote, though in degree than other gases, tends sooner or later to disap and matters would resume their former condition if the is not re-introduced in sufficient quantity. The treatm therefore, is long, lasting for months, but finally, e because the absorbent power of the pleura is minimis because the danger of the lung's distending anew bec less probable, we may consider the cure as complete. fessor Forlanini was able to produce clinical proofs o efficacy of his treatment and in the discussion w followed to make out a "good case" for giving his meth trial.

Are Medicines Groceries?

It would seem so according to the Venetian Cour Appeal. Certain pharmacists in Venice sued three gro of that city for having, in contravention of the "Co Sanitàrio," sold "specialità medicinali" (special medici and the Pretore Urbano (city sheriff) found the said gro guilty and fined them in 200 lire (£8), with an orde compensate the pharmacists for the losses sustained grocers appealed, and on July 11th, after a long discus judgment was given in their favour, the court affirming grocers can sell all "specialità medicinali" which have supplied to them by the houses which manufacture same. Evidently the article of the "Codice Sanita dealing with the question requires revision!

July 12th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Lowered Gastric Secretion.

AT a recent meeting of the Medical Society Dr. A read an interesting address on Lowered Gastric Secretion the course of which he said that the view recently adva that the gastric secretion can be dispensed with did commend itself to him. The presence of the gastric juice the duodenum stimulates indirectly the pancreas and regulates the movements of the stomach. Dr. Aldor refer to a condition where the gastric juice is absent with apparent cause. Depression, neurasthenia, and hyste produce suppression of this secretion; diseases of the bra spinal cord, as well as arterio-sclerosis, are factors bringing about a defect of secretion of the stomach. T absence of the hydrochloric acid in acute inflammat conditions of the stomach is a wise provision, as if pres it would cause considerable irritation to the muco Insufficient gastric juice at times produces diarrh and particles of undigested food, especially protei are found in the stools. It is injudicious, in Dr. Ald opinion, to give hydrochloric acid in carcinoma the stomach, as the acid is a source of irritatio Poor gastric digestion will bring about poor intestin digestion. No two individuals can be considered to requ the same amount of hydrochloric acid, so that there is standard as to the amount of acid necessary for digesti in all people. Dr. Aldor holds that the stomach can educated to do substantial work; therefore a mixed di should be given and it is not to be taken in small quantities frequent intervals, although in some instances it is necess to give the meals frequently. He is inclined to think th a more normal digestion is obtained with pyloroplasty tha with gastro-enterostomy.

Radiotherapy.

At the last meeting of the Dermatological Society con siderable attention was devoted to the present status o radiotherapy. Broadly speaking, the view of the meeti difficulty in a form that has occasioned much anxiety, for when it has expended its funds on the training of suitable women as district midwives it has found it no easy matter to place them. "In many cases," says the last annual report (1906), "the barest living is offered, with no possibility of anything whatever being put aside for old age or even the necessary clothing or holidays; and this is supposed to suffice for a woman whose possession of the certificate of the Central Midwives Board shows her to have good abilities and to be fitted for responsible and very arduous work."

The object of this report is to furnish information, not to suggest remedies. The matter, however, is urgent and the subcommittee earnestly hopes that some efficient means of overcoming the present difficulties will speedily be devised.

APPENDIX.

In the accompanying tables the various areas from which returns have been received are grouped together as follows:—

Group I. includes eight entire administrative county areas, with a combined population of 2,939,148, from which full returns have been received.

Group II. includes 32 entire administrative county areas with a combined population of 11,956,860, from which the returns which have been received, whilst not so full as in the former case, are still of considerable value.

Group III. includes 23 county borough areas, with a combined population of 4,288,345, from which full returns have been received.

Group IV. includes 37 county borough areas, with a

supporting the adoption of the report, said that the Government had decided to comply with this suggestion. It also proposed to place all the hospitals in the State under the control of a representative board, which would allocate the hospital grant according to individual requirements.—Hospital Saturday in Sydney has become a recognised institution and this year £5546 were collected, an increase of over £600 on the best previous collection.—The inspector of charities for Victoria recently submitted to the Premier a memorandum suggesting the establishment of paying hospitals intermediary between charity hospitals and private hospitals, where the charges would be lower than at the latter and the fees charged by the medical attendants less. The acting Premier has stated that he is not altogether in favour of the suggestion but admits that there is a great deal to be said for it.—At the last meeting—the second held—of the recently formed Hospitals and Charities Association of Victoria it was reported that 32 institutions had joined the association. A joint subcommittee of the association and the Victorian Trained Nurses' Association was appointed to coöperate in arrangements for training nurses, and to deal with all matters arising between the hospital authorities and the nurses. A subcommittee was appointed to inquire into a statement in the report of the inspector of charities that there were seven institutions supported by Government grants and public subscription which treated 40 patients only amongst them and employed 36 persons to attend these 40 patients.—His Excellency the Governor recently opened a new hospital for incurables at Ryde. The institution is entirely due to private philanthropy and began in a very small way.

Australasian Massage Association.

The first annual meeting of delegates to the Australasian Massage Association was opened in Sydney recently, Dr. J. W. Springthorne of Melbourne presiding. The membership of the association was stated to be 302. It was a condition of membership that no one should act as a masseur except under medical supervision and that no member should prescribe remedies unless he were a registered medical practitioner.

Claim by a Chinese Herbalist.

An amusing case was heard in the Central police court, Sydney, on April 16th when a Chinese herbalist proceeded against a former patient to recover £27 odd for services and goods. He had treated him for a sore on the lip, which was subsequently excised by a medical practitioner. The treatment recommended was to rub salt on a cow's nose and then to rub the salt on the patient's lip. The plaintiff was non-suited.

Obituary.

Dr. Roland MacLean of Narracoorte, South Australia, died recently at Seymour, Victoria, where he was spending a holiday. He was only 35 years of age and died from heart failure during a severe attack of influenza.—Mr. Charles Dixon was found dead at Double Bay, Sydney, with a bottle of cyanide of potassium beside him. He was 81 years of age and was stated to be destitute, though he had once been very well off and had lost two fortunes in mining speculations. A verdict of Suicide was returned by the coroner.

June 3rd.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of the above society was held on July 10th, Dr. G. F. Blandford, the President, being in the chair. 21 directors were present. The deaths of Sir William Broadbent and Dr. Robert Barnes were reported; both had held the office of director. The secretary was directed to send letters of condolence to Lady Broadbent and to Mrs. Barnes. Two new members were elected. Since the last quarterly court one of the widows, an annuitant of the charity, had died; her husband paid a life subscription fee of £26 5*s.* and the widow had received in grants the sum of £490. Six letters had been received from widows of medical men asking for relief, but in each instance this had to be refused as their husbands had not been members of the society. The sum of £1300 10*s.* was voted for the half-yearly grants to the 49 widows and 20 orphans at present on the books of the society. Membership is open to any registered medical practitioner who at the time of his election is residing within a 20-mile radius of Charing Cross. Full particulars may be obtained from the secretary at 11, Chandos-street, Cavendish-square, London, W.

Medical News.

UNIVERSITY OF LEEDS.—The degrees of F
of Medicine and Bachelor of Surgery were con
July 11th by the Vice-Chancellor on the following :-

James Paley Bibbey and William Laud Dibb.

The Diploma of Public Health has been conferre
following :—

William Scatterty, M.D. Aberd., and Fred. Augustus Shar

The following pass lists have been issued :—

SECOND EXAMINATION FOR THE DEGREES OF M.B., C
Part I. Anatomy and Physiology.—C. S. Brown and C. G.
Part II. Materia Medica and Pharmacy.—J. P. Brown,
J. B. Fisher, W. S. Hart, H. V. Lamb, N. V. Mitton, B. A.
G. V. Stockdale, and N. S. Twist.

FINAL EXAMINATION FOR THE DEGREES OF M.B., CH
Part I. W. H. Butler and H. Vallow.

FIRST PROFESSIONAL EXAMINATION FOR THE DIPLOMA O
E. Howden and F. C. Wilson.

UNIVERSITY OF GLASGOW.—The followin
satisfied the examiners in the fourth (final) pro
examination for M.B., Ch.B. :—

Wallace Wright Adamson, George Victor Anderson,
Hamilton Arnott, David Arthur, B.Sc., Herbert Bertra
Inglis Binning, William Brown, M.A., B.Sc., James G
Thomas Hay Campbell, Robert Peploe Cartwright, Thoma
Copestake, Alexander Johnston Couper, Andrew Donaldso
James Robert Craig, Charles Adolphus Crichlow, Nelso
Harold Windley Dempster, John Alexander Doctor,
Duncan, William Hunter Duncan, Allan Dunsmuir, Leon
Dunstone, Alexander Wylie Eadie, William Marley

James Hutton, Thomas Miller, M.A., Daniel M'Kinlay Reid, G
Waugh Scott, John Steedman, Campbell Kay Stevenson, Law
Storey, David Alexander Thomson, M.A., Hugh Johnstone Thom
Samuel Wilson, M.A., and Matthew Young.

In Practice of Medicine and Clinical Medicine.—John M'Vitti
Horatio Matthews.

In Midwifery.—Allison David M'Lachlan and Alexander Scott.

FOREIGN UNIVERSITY INTELLIGENCE
Berlin: Dr. Morgenroth has been recognised as *privat-do*
of Hygiene and Dr. F. Nicolai as *privat-docent* of Physiolo
—*Breslau:* Dr. Strecker has been recognised as *privat-do*
of Anatomy and Biology.—*Düsseldorf* (*Academy of Pract*
Medicine): Dr. O. Lubarsch has been appointed Professo
Pathological Anatomy in succession to Dr. M. B Schm
who goes to Zürich.—*Freiburg:* Dr. W. Straub of Würzb
has been appointed Professor of Pharmacology.—*Gene*
Dr. O Beuttner has been appointed Professor of Midwif
and Gynæcology in succession to the late Dr. A. Jentzer.

Alderman Fleetwood Pritchard seconded the motion.

Mr. Malcolm, the treasurer, speaking in support of the council, said that *everything must be subordinate to financial* considerations, which Dr. W. Coode Adams on Christian principles warmly denied.

Mr. J. S. Bergheim and Mrs. Meer, on behalf of the Ladies' Association, supported the motion and strongly advocated the retention of the present staff arrangements. They were listened to much more readily than was Mr. C. W. Sawbridge, who spoke no less strongly against it; but at this stage, when the debate was waxing somewhat heated, Mr. Donald Macmillan rose with a pacific suggestion that an arrangement might yet be come to agreeable to all parties. If the motion were put to the meeting it would of necessity cause disastrous dissension in their midst, he said, while he did not consider that there were enough facts before the governors to guide them in voting. He therefore proposed as an amendment that a committee of subscribers should be appointed to inquire and to report as to what course was most advantageous to the hospital and the people of Hampstead, and that it should have power to confer with the hospital council, the *King's Fund, and the local branch of the* British Medical Association, and that the meeting should stand adjourned until it was ready to make its report.

Dr. E. Collingwood Andrews tried to obtain a pledge from the council that in the interim the amalgamation proposals should be suspended but this was not fully given, although the chairman of the council promised that no more steps would be taken than those to which the council was already pledged.

At the request of the mover of the amendment, who speedily found a seconder, the Mayor withdrew his motion, and after further discussion a committee of six governors, known not to be active partisans in the controversy, was appointed. The amendment on being put to the meeting was carried with two dissentients, several governors abstaining from voting.

Note.—In our article on the Hampstead Hospital in last week's issue the sentence concerning the numbers of out-patients should have run: "at the North-West London Hospital there had been an out-patient practice of about 23,000 attendances a year, whilst that at Hampstead did not much exceed 2300." By an error of type the numbers were considerably multiplied, a mistake which must have been immediately perceived by all interested

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Election of President.

A quarterly meeting of the Council was held on July 11th, the President, Mr. Henry Morris, being in the chair.

The President reported the result of the election of members of the Council as already published in The Lancet of last week.

Mr. C. W. Mansell Moullin, Mr. F. S. Eve, Mr. W. Bruce Clarke, and Mr. Charters J. Symonds were introduced, made declarations in the terms of the oath prescribed by the charter of 1800, and took their seats in the Council.

On the recommendation of the museum committee it was resolved that Volume III. of the second edition of the Catalogue of the Physiological Series of Comparative Anatomy in the museum should be offered for sale at 12s. per copy. The museum committee also submitted the revised copy of Part I. (Man) of the Osteological Catalogue.

A Member of the College, whose name has already been removed from the Medical Register, was ordered to be removed from being a Member of the College.

The Council referred to the committee of management's resolutions adopted by the General Medical Council on May 30th on the subject of the instruction of students in practical midwifery, and also the resolutions and recommendations of the General Medical Council in reference to professional education and professional examination.

A letter was read from Messrs. Dundas and Wilson reporting that by the death of Miss Moncrieff Arnott on June 10th the legacy of £1000 bequeathed to the College by Mr. James Moncrieff Arnott (who was President of the College in 1850) will become payable to the College free of legacy duty on Nov. 11th next, and reporting, by direction of Miss Arnott's executors, that by her will she requests them *to offer to the College the portrait in oil* of her father which is in the mansion house of Chapel, Fifeshire. The President stated that he had accepted the portrait on behalf of the Council and had conveyed to Miss Arnott's executors the assurance that the presentation of this portrait of a past President of the College would be warmly welcomed.

The Council then proceeded to elect professors and lecturers for the ensuing year and the following were appointed:—Hunterian professors: W. Sampson Handley, one lecture on Therapeutic Criteria in Cancer; W. F. Victor Bonney, three lectures on a Study of the Connective Tissues in Carcinoma and in Certain Pathological Conditions Preceding its Onset; Donald J. Armour, three lectures on the Surgery of the Spinal Cord and its Membranes; Arthur R. Thompson, two lectures on the Anatomy of the Long Bones relative to Certain Fractures; and Frank C. Shrubsall, three lectures on the Physical Anthropology of the Pigmy and Negro Races of Africa. Arris and Gale lecturers: F. A. Bainbridge, one lecture on the Pathology of Acid Intoxication; and Major Greenwood, jun., two lectures on the Physiological and Pathological Effects which Follow Exposure to Compressed Air. Erasmus Wilson lecturers: Samuel G. Shattock, one lecture on Ovarian Teratomata; J. W. H. Eyre, one lecture on the Surgical Importance of the Pyogenetic Activities of Diplococcus Pneumoniæ; and L. S. Dudgeon, one lecture on Infection of the Urinary Tract due to Bacillus Coli.

Mr. Henry Morris was re-elected President and Mr. Rickman J. Godlee and Mr. W. Watson Cheyne were appointed Vice-Presidents.

The President stated that the vacancy on the Court of Examiners occasioned by the resignation of Mr. C. H. Golding-Bird would be filled at the ordinary Council on July 25th.

The President further stated that the vacancies on the Board of Examiners in Dental Surgery occasioned by the resignation of Mr. A. Pearce Gould and by the expiration of the period of office of Mr. W. B. Paterson would be filled at the ordinary Council on July 25th. Mr. Paterson will offer himself for re-election.

A letter was read from Mr. C. R. Hewitt, stating that he has accepted a librarianship in the Royal Society of Medicine and tendering his resignation of the post which he has been holding in the College. The Council accepted the resignation and expressed its appreciation of the services which he had rendered to the College during 22 years.

The Secretary reported the death, on June 21st, of Professor Edward Hallaran Bennett, Honorary Fellow of the College. The President was requested to convey the sympathy and condolence of the Council to the widow and family.

The Secretary reported that Sir John Tweedy had presented to the College Rymer's "Fœdera" in 20 volumes, folio, published in 1711. The best thanks of the Council were given to Sir John Tweedy for his interesting and valuable gift.

THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

The seventy-fifth annual meeting of the British Medical Association will be held at Exeter from July 30th to August 3rd. The following is a brief programme of the proceedings.

The President of the Association for 1907–08, Dr. Henry Davy, physician to the Royal Devon and Exeter Hospital, will be inducted on Tuesday afternoon, July 30th, and in the evening will deliver his Presidential Address and welcome delegates from the colonial branches and distinguished foreign guests. The Middlemore prize will be presented at the evening meeting to Mr. Sydney Stephenson.

The Address in Medicine will be given on Wednesday afternoon by Dr. W. Hale White, physician to Guy's Hospital, who will advance "a plea for accuracy of thought in medicine." The Address in Surgery will be delivered by Mr. H. T. Butlin, consulting surgeon to St. Bartholomew's Hospital and formerly treasurer of the British Medical Association, on Thursday afternoon; his address will be "on the contagion of cancer in human beings, auto-inoculation." The popular lecture, a comparatively new feature in

President of the new section. Dr. Burton Brown, in reply, thanked the society of Queen's College for its courtesy in inviting the members of the Therapeutical Section to that College and in placing rooms at the disposal of those who desired to remain until Monday. Dr. R. C. B. Wall, through whose good offices the visit was undertaken, acted as cicerone and showed every attention to the party.

Western Eye Infirmary, Exeter.—Colonel Garratt, on July 12th, in the presence of a large gathering, formally unveiled a memorial erected in the main hall of the institution, to the memory of the late Miss G. Kinninmont, for 16 years matron of the infirmary, who died suddenly last year. The memorial consists of a tablet of alabaster, richly ornamented, bearing a suitable inscription.

Royal College of Surgeons in Ireland: Fellowship Examination.—Notice is hereby given that on and after Jan. 1st, 1910, all examinations for the Fellowship of this College will be conducted under the scheme of examination now known as Grade 1. No candidate after the above date will in any circumstance be admitted to examination for the Fellowship of this College under the scheme now known as Grade 2, which will then cease to be used.

St. Helena.—In his report for the year 1906 Lieutenant-Colonel H. L Gallwey, Governor of the island, states that the estimated civil population on Dec. 31st was 3526. There were 118 births during the year, of which three were stillborn and 37 illegitimate. Now that the troops have been withdrawn the number of births under the latter category will undoubtedly be less in future. The birth-rate works out at 33·1, as against 35·9 in 1905. 46 deaths occurred during the year, the death-rate being 11·9 per 1000, as compared with 14·5 in 1905. The general health of the colony was excellent and there were no epidemics of any zymotic disease. There were 104 admissions to the hospital during the year, this being the smallest number recorded since the inauguration of the institution. Until a few years ago the islanders had an aversion to going to hospital. Their feelings on this point, however, are quite the reverse now, thanks mainly to the excellent and efficient system under which the hospital is conducted by the colonial surgeon, Dr. W. J. J. Arnold, and his staff of nurses. This tendency of the islanders to go to hospital when necessary, instead of avoiding such a step, is satisfactory under the conditions now existing in St. Helena. When the troops were withdrawn in October, 1906, the colony was left with only one medical man and upon his shoulders falls the responsibility of the medical care of the population. Consequently, it is desirable to move all serious cases to the hospital where they can be immediately under the eyes of the colonial surgeon and the nursing staff. The hospital sustained a severe loss during the year by the retirement through illness of Miss Williams, the lady superintendent of the staff, who had occupied that position for over 11 years. She has been succeeded by Miss Hart, late matron at Kokstad Hospital, South Africa. The colonial surgeon was granted six months' leave of absence, during which period his duties were performed by Mr. H. E. Scoones.

International Housing Congress.—The annual congress (the eighth) will take place this year in London. The previous meeting places have been Paris, Antwerp, Bordeaux, Brussels, Paris again, Düsseldorf, and Liége. The president of the congress will be Sir Henry Campbell-Bannerman, and there are numerous notable vice-presidents. The congress will be held in the Caxton Hall, Caxton-street, Westminster, and the programme has been arranged to cover from August 3rd to 10th. It is hoped that the Right Hon. John Burns, M.P., President of the Local Government Board, will officially welcome the delegates at the opening session. On August 8th the delegates will leave London and will pay visits on that day and the two following days to Sheffield, Liverpool, Port Sunlight (Birkenhead), and Bournville (Birmingham) to inspect the Cottage Exhibition and municipal housing schemes, the dwellings for the poorest of the poor, and the model villages. On one of the days during the congress a visit will be paid also to the Cottage Exhibition and first garden city at Letchworth and visits will also be made to inspect municipal and other housing schemes in and around London. Invitations to send official representatives have been given to the Governments of France, Germany, Austria, Belgium, Holland, Italy, Sweden, Norway, Spain, and other European countries, the United States, South America, Japan, and the Governments of the British Colonies, and also to the provincial, county, and town councils of those countries, to the local authorities throughout Great Britain and Ireland, and to various associations and private persons specially interested in the subject of housing. The membership subscription is £1 1*s.* for each delegate or member. The chairman is Mr. William Thompson, the vice-chairman is Mr. T. C. Horsfall, and the secretary is Mr. Henry R. Aldridge, all of whom are British members of the International Housing Committee. Councillor W. G. Wilkins, J.P., will act as treasurer to the congress. Any communications on the subject will reach the secretary if addressed to him at 432, West Strand, London, W.C.

Water-supply of Bodmin.—The Local Government Board has declined to sanction the water scheme proposed by the Bodmin (Cornwall) district council on the ground of inadequacy.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Alton Military Hospital Bill.

The Alton Military Hospital Bill, which is being proceeded with as a private Bill, has been read a second time in the House of Commons.

The University of Durham Bill.

The University of Durham Bill, which has been introduced into the House of Commons by Mr Hills, makes several proposals "to enable the University to discharge its present functions more efficiently." It is proposed to set up a body of seven commissioners whose names are embodied in the Bill They include the Duke of Northumberland and Sir William Church Their duties under the Bill are to make various regulations of a specified nature with regard to the constituent bodies of the University.

HOUSE OF COMMONS.

Wednesday, July 10th.

Belfast Corporation and the Forster Green Hospital.

Mr. Devlin asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the decision of the Belfast Corporation sanctioning an arrangement for ten years with the committee of management of the Forster Green Hospital for Consumption, under which arrangement the hospital authorities were to reserve 25 beds for patients nominated by the corporation and approved as suitable by the medical superintendent of the hospital, the corporation to pay the sum of 35*s* per week per bed and two members of the corporation to be on the board of governors of the hospital, whether he was aware that the Forster Green Hospital was situated in a hollow and was built and equipped over 30 years ago, before the value of an elevated situation and open-air treatment for consumption became recognised by the best authorities on the disease, and at the present time was quite unsuitable for the treatment of tuberculous patients, whether he was aware that the sum agreed upon was 10*s* per bed per week in excess of that which was the basis of negotiations between the parties in 1903, and that the opinion of an expert taken by the corporation on the Forster Green Hospital and site was suppressed by the corporation public health committee, despite the appeals of several councillors for its publication; and whether, seeing that it was estimated that the cost of establishing a municipal consumptive hospital for Belfast on a suitable site and equipped in a thoroughly up to-date manner for 25 patients, would be £12,500, which would be cheaper than the present arrangement, and that the present arrangement was part of a scheme to help the Forster Green Hospital until the sum of £40,000, on the subscription of which a large bequest was contingent, was forthcoming, and that the death rate from consumption in Belfast was exceptionally high, and seeing that the present arrangement was opposed to the public interest, he would refuse to sanction it and order an inquiry into the whole question.—Mr. Birrell (by written answer) replied The Local Government Board has received an application from the Belfast corporation for sanction to an arrangement with the committee of the Forster Green Hospital on the terms indicated in the first part of the question. A protest has been made to the Board on substantially the same grounds of objection as are recited in the question and the matter is at present under the Board's consideration.

The Housing of the Working-classes.

Sir Walter Foster asked the Prime Minister whether, in consideration of the fact that the Select Committee appointed last year to consider the question of housing reported in December last, and also that a Bill was promised in the King's speech on the opening of Parliament this year, he could give some assurance that a measure for the better housing of the working-classes would be included in the programme for next session.—Sir Henry Campbell Bannerman furnished the following answer: His Majesty's Government is fully alive to the importance of this question, and my right honourable friend may be assured that it is its intention to introduce legislation dealing with the better housing of the working classes at the earliest practicable moment. I may add that no effort on its part will be wanting to frame a measure which shall be adequate to the necessities of the case.

Croydon Mental Hospital (Annual Report for the Year ending March 31st, 1907).—The annual report is made up to March 31st, 1907, but the statistical tables are for the year ending Dec. 31st, 1906. There were 161 patients (89 males and 72 females) admitted during the year 1906. Dr. E. S. Passmore states that of these there was a history of intemperance in 37 (26 males and 11 females), or nearly 23 per cent.; a history of venereal disease in 8·7 per cent., and hereditary influence in 31 per cent. He goes on to say that "if our feeble-minded and mental undesirables were prevented from propagating their species a large number of asylums in the country could be closed." The medical superintendent gives a table showing the increase of patients chargeable to Croydon since 1902. The yearly ratio of accumulated cases is 20·66 women and 8·44 men up to December last. During the year 79 patients were discharged (42 males and 37 females); of these, 54 (32 males and 22 females) are reported as "recovered," 22 (nine males and 13 females) as "relieved," and three (one male and two females) as "not improved." There were 51 deaths (33 males and 18 females) during the year 1906, and of these 13 were due to general paralysis and ten to pulmonary tuberculosis. The maintenance rate remains at 14*s*. The farming and gardening account shows a credit balance of £103. Owing to overcrowding on the female side in the main building the isolation hospital is being temporarily used to accommodate 18 female patients. There were no cases of infectious disease during the year.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8054 births and 3774 deaths were registered during the week ending July 13th. The annual rate of mortality, which had been equal to 12·5 per 1000 in each of the two previous weeks, declined to 12·3 in the week under notice. During the 13 weeks of last quarter the death-rate in these towns averaged 15·1 per 1000, the rate in London during the same period being 14·6. The lowest rates in the 76 towns last week were 3·5 in Hornsey, 5·1 in Leyton, 6·2 in King's Norton, and 7·0 in Walthamstow; the highest rates were 17·7 in Stockon-on-Tees, 17·8 in Preston, 18·6 in Hanley, 19·1 in Oldham and in Tynemouth, and 19·4 in Bootle. The 3774 deaths in the 76 towns showed a decline of 79 from the number in the previous week, and included 341 which were referred to the principal epidemic diseases, against 427 and 366 in the two preceding weeks; of these, 127 resulted from measles, 103 from whooping-cough, 39 from diarrhœa, 33 from diphtheria, 29 from scarlet fever, and ten from "fever" (principally enteric), but not any from small-pox. No death from any of these epidemic diseases was registered last week in Southampton, Burnley, Swansea, Huddersfield, Hornsey, or in eight other of the 76 towns; the annual rates from these diseases, however, ranged upwards to 3·3 in Devonport, 3·7 in Derby, 4·7 in Wigan, and 5·4 in Walsall. The deaths from measles, which had been 158 and 130 in the two previous weeks, further fell to 127 in the week under notice; the death-rates from this disease ranged upwards to 1·4 in Merthyr Tydfil, 1·9 in Reading, 3 3 in Derby, 3·5 in Wigan, and 4·3 in Walsall. The fatal cases of whooping-cough, which had been 136 and 109 in the two preceding weeks, further decreased to 103 last week, the highest death-rates from this cause being 1·2 in West Ham and in Wigan and 1 7 in Barrow-in-Furness. The 39 deaths from diarrhœa showed a further slight decline from the comparatively small numbers in recent weeks; in Devonport the death-rate from this disease was 2·0 per 1000. Of the 29 fatal cases of scarlet fever, 11 belonged to London; and of the 33 deaths from diphtheria, eight were recorded in London and three in Liverpool. Not more than one death from "fever" was registered during the week under notice in any of the 76 towns. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had risen from 2655 to 3193 in the nine preceding weeks, had further increased to 3276 at the end of last week; 493 new cases were admitted during the week, against 414, 422, and 504 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 156 and 148 in the two preceding weeks, further declined to 139 in the week under notice, but were six in excess of the corrected average number in the corresponding week of the five years 1902–06. The causes of 35, or 0·9 per cent., of the deaths registered in the 76 towns during the week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, Newcastle-on-Tyne, Salford, Leicester, and in 52 other of the 76 towns; the proportion of uncertified deaths, however, showed considerable excess in Liverpool, Birmingham, Sheffield, and Barrow-in-Furness.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 17·3, 15·0, and 14·5 per 1000 in the three preceding weeks, further declined to 13·7 in the week ending July 13th, but exceeded by 1·4 per 1000 the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 9·0 in Aberdeen and 10·6 in Paisley, to 17·3 in Dundee and 22·5 in Perth. The 475 deaths in these towns showed a decrease of 29 from the number in the preceding week, and included 60 which were referred to the principal epidemic diseases, against 84, 76, and 59 in the three preceding weeks. These 60 deaths were equal to an annual rate of 1·7 per 1000, which exceeded by 0·6 per 1000 the rate from the principal epidemic diseases in the 76 large English towns; they included 22 which were referred to whooping-cough, 14 to "fever," 12 to diarrhœa, eight to measles, two to scarlet fever, and two to diphtheria, but not any to small-pox. The fatal cases of whooping-cough, which had continuously declined from 57 to 18 in the six preceding weeks, rose again to 22 in the week under notice, and included 12 in Glasgow, five in Edinburgh, three in Dundee, and two in Paisley. The deaths referred to "fever," which had been 21 and 18 in the two previous weeks, further fell last week to 14, of which six were registered in Glasgow, four in Edinburgh, two in Leith, and one each in Dundee and in Paisley; all these 14 deaths were certified as from cerebro-spinal meningitis. The 12 fatal cases of diarrhœa showed a slight increase over the number in the preceding week, and included three in Glasgow, three in Edinburgh, two in Dundee, and two in Paisley. The deaths from measles, which had been four and five in the two previous weeks, further rose last week to eight, of which seven occurred in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 72 and 80 in the two preceding weeks, further increased to 88 in the week under notice, and exceeded by 30 the number in the corresponding week of last year. The causes of 22, or 4·7 per cent., of the deaths registered in the eight towns during the week were not certified or not stated; in the 76 English towns the proportion of uncertified deaths did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 20·8, 19 5, and 18·3 per 1000 in the three preceding weeks, rose again to 21·0 per 1000 in the week ending July 13th. During the 13 weeks of last quarter the death-rate averaged 25·4 per 1000, the rates during the same period being 14·6 in London and 17·1 in Edinburgh. The 157 deaths of Dublin residents registered during the week under notice showed an increase of 20 over the number in the preceding week, and included 14 which were referred to the principal epidemic diseases, against 11 and 19 in the two preceding weeks; of these, seven resulted from whooping-cough, five from diarrhœa, and two from measles, but not any from small-pox, from scarlet fever, from diphtheria, or from "fever." These 14 deaths were equal to an annual rate of 1·9 per 1000, the rate during the same week from the principal epidemic diseases being 1·1 in London and 2·1 in Edinburgh. The seven fatal cases of whooping-cough were slightly fewer than the number in the previous week, while the five deaths from diarrhœa considerably exceeded the number in any recent week. The 157 deaths from all causes in Dublin last week included 30 of children under one year of age and 42 of persons aged upwards of 60 years, these numbers being respectively six and ten in excess of those returned in the previous week. Four inquest cases and three deaths from violence were registered; and 58, or nearly 37 per cent., of the deaths occurred in public institutions. The causes of eight, or 5·1 per cent., of the deaths in Dublin last week were not certified; the percentage of uncertified

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.*

Coombs, Carey F., M.D., B.S. Lond., has been appointed Demonstrator in Dental Bacteriology at University College, Bristol.

Dimock, Horace, M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Surgeon at Addenbrooke's Hospital, Cambridge.

Dowling, E. A. G., L.R.C.P., M.R.C.S., L.D.S., has been appointed Lecturer in Dental Anatomy, Physiology, and Dental Histology at University College, Bristol.

Elgood, Olive, M.S. Lond., has been appointed Honorary Anæsthetist to the Birmingham and Midland Dental Hospital.

Evans, William Owen, L.R.C.P., L.R.C.S., L.M. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer and Medical Officer to the Workhouse by the Pontardawe (Glamorganshire) Board of Guardians.

Eyre, J. W. H., M.D., M.S. Durh., has been appointed Bacteriologist to Guy's Hospital.

Friend, Julius, L.S.A., has been appointed Medical Officer to the No 2 District by the Leeds Board of Guardians.

Hitchcock, Norman, M.B., B.S. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer to the Brixton Dispensary.

Jones, John Arnold, M.B., Ch.B. Vict., F.R.C.S. Edin., has been appointed Honorary Assistant Aural Surgeon to the Manchester Eye and Ear Hospital.

Lochrane, Frank J., M.D., B.S. Glasg., has been appointed Honorary Gynæcologist to the Derbyshire Royal Infirmary.

McEwan, Peter, M.B., Ch.B., F.R.C.S. Edin., has been appointed Resident Surgical Officer at the Bradford Royal Infirmary.

Pedley, F. Newland, F.R.C.S. Eng., L.D.S., has been appointed Consulting Dental Surgeon to Guy's Hospital.

Perry, Frederick W., L.D.S., has been appointed Demonstrator in Dental Anatomy, Physiology, and Dental Histology at University College, Bristol.

Pillin, H. L., L.D.S. R.C.S. Eng., has been appointed Dental Surgeon to Guy's Hospital.

Price, Henry J., F.R.C.S. Eng., has been appointed Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 38, and to be attached more particularly to Braintree, Chelmsford, Colchester, Dunmow, Halstead, Harwich, and Maldon County Courts.

Rowlands, R. P., F.R.C.S. Eng., M.S. Lond., has been appointed Assistant Surgeon-in-Charge of the newly sanctioned Orthopædic Department at Guy's Hospital.

Watson, C. Gordon, F.R.C.S. Eng., has been appointed Surgical Registrar to St. Bartholomew's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birmingham, University of.—Walter Myers Travelling Studentship. Value £150.

Bolingbroke Hospital.—Assistant Surgeon.

Bradford Children's Hospital.—House Surgeon. Salary £100.

Cambridge, Cambridgeshire Lunatic Asylum, Fulbourn.—Second Assistant Medical Officer, unmarried. Salary £120 per annum, with board, lodging, and attendance.

Cardiff Infirmary (General Hospital).—House Physician for six months. Salary £30, with board, residence, and laundry.

Carmarthenshire Infirmary.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, attendance, &c.

Chelsea Hospital for Women, Fulham-road, S.W.—Clinical Assistant for three months.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—House Physician, for six months. Salary at rate of £50 per annum, with board, washing, and residence.

Coventry and Warwickshire Hospital.—Junior House Surgeon for six months, renewable. Salary £60 per annum, with rooms, board, washing, and attendance.

Devonport, Royal Albert Hospital.—Resident Medical Officer. Salary £100 per annum, with apartments, board, fuel, and lights.

Dover, Royal Victoria Hospital.—House Surgeon, unmarried. Salary £100 a year, with board, lodging, and washing.

Egypt, Public Health Department.—Sub-Inspector of Ophthalmic Hospitals.

Gloucester, General Infirmary and the Gloucestershire Eye Institution.—Assistant House Surgeoncy for six months. Salary at rate of £30 per annum, with board, residence, and washing.

Halifax, Royal Halifax Infirmary.—Second House Surgeon. Salary £100 per annum, with residence, board, and washing.

Hospital for Sick Children, Great Ormond-street, London, W.C.—House Physician, House Surgeon, Assistant Casualty Officer.

Hull, Royal Infirmary.—Casualty House Surgeon. Salary £50, with board and lodging.

Italian Hospital, Queen-square, London, W.C.—Honorary Assistant Physician.

deaths during the week did not exceed 0·1 in London, while in Edinburgh it was 7·7. The 104 deaths in Belfast included ten which were referred to cerebro-spinal meningitis or cerebro-spinal fever.

VITAL STATISTICS OF LONDON DURING JUNE, 1907.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 7·2 per 1000 of the population, estimated at 4,758,218 persons in the middle of the year; the rates in the three preceding months were 6·6, 6·9, and 7·1 per 1000 respectively. The lowest rates last month were recorded in Paddington, Chelsea, the City of Westminster, Hampstead, and Holborn; and the highest rates in Hackney, Shoreditch, Bethnal Green, Stepney, and Woolwich. No case of small-pox was notified in London during the month. The prevalence of scarlet fever showed a marked increase over that recorded in either of the two previous months; this disease was proportionally most prevalent in Hackney, Shoreditch, Bethnal Green, Stepney, Bermondsey, and Woolwich. The Metropolitan Asylums hospitals contained 2975 scarlet fever patients at the end of last month, against 2614, 2586, and 2777 at the end of the three preceding months; the weekly admissions averaged 390, against 312, 332, and 368 in the three preceding months. Diphtheria was considerably less prevalent than it had been in any other month of this year; among the various *metropolitan* boroughs this disease showed the greatest proportional prevalence in Fulham, Shoreditch, Bethnal Green, Bermondsey, Deptford, and Greenwich. There were 806 diphtheria patients in the Metropolitan Asylums hospitals at the end of last month, against 1012, 946, and 933 at the end of the three preceding months; the weekly admissions averaged 107, against 136, 119, and 121 in the three preceding months. The prevalence of enteric fever showed a slight increase over that in the preceding month; this disease was proportionally most prevalent in Fulham, St. Marylebone, Hampstead, Bethnal Green, Southwark, Camberwell, and Woolwich. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 93, 66, and 47 at the end of the three preceding months, had risen again to 57 at the end of last month; the weekly admissions averaged 13, against 13, 12, and nine in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Shoreditch, Bethnal Green, Stepney, Battersea, and Woolwich. The 16 cases of puerperal fever notified during the month included four in Islington and two in Lambeth. Of the 17 notified cases of cerebro-spinal meningitis, four belonged to Stepney, two to Poplar, and one to each of 11 other boroughs.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the four weeks ending June 29th the deaths of 4451 persons belonging to London were registered, equal to an annual rate of 12·2 per 1000; in the three preceding months the rates had been 16·9, 15·8, and 14·0 per 1000. The death-rates last month ranged from 7·4 in Hampstead, 7·9 in Lewisham, 8·3 in Stoke Newington, 9·3 in Woolwich, 9·5 in Paddington, and 9·8 in Greenwich, to 15·0 in Shoreditch, 15·4 in Holborn, 15·6 in Poplar, 18·0 in Southwark, 18·6 in the City of London, and 19·5 in Finsbury. The 4451 deaths from all causes in London last month included 565 which were referred to the principal infectious diseases; of these, 229 resulted from measles, 47 from scarlet fever, 41 from diphtheria, 180 from whooping cough, seven from enteric fever, one from ill-defined pyrexia, and 60 from diarrhœa. The lowest death-rates from the principal infectious diseases were recorded in the Cities of London and Westminster, and in the boroughs of Hampstead, Holborn, and Lewisham; and the highest rates in Fulham, Finsbury, Shoreditch, Poplar, and Southwark. The 229 fatal cases of measles were 30 in excess of the corrected average number in the corresponding periods of the five preceding years; the greatest proportional mortality from this disease occurred in Fulham, Chelsea, St. Pancras, Finsbury, Southwark, Bermondsey, and Lambeth. The 47 deaths from scarlet fever were seven below the corrected average; among the various metropolitan boroughs this disease was proportionally most fatal in St. Marylebone, Finsbury, Stepney, Southwark, and Bermondsey. The 41 fatal cases of diphtheria were slightly below the corrected average number; the highest death-rates last month from this disease occurred in Bethnal Green, Poplar, Bermondsey, Deptford, and Woolwich. The 180 deaths from whooping-cough exceeded by 66 the average for the corresponding period of the five preceding years; the greatest proportional mortality from this disease occurred in Islington, Stoke Newington, Finsbury, Shoreditch, and Poplar. There were only eight deaths from "fever" last month, against an average of 19 in the corresponding period of the five preceding years; these eight deaths belonged respectively to Hampstead, Fulham, St. Pancras, Islington, Lambeth, Wandsworth, Greenwich, and Woolwich. The 60 fatal cases of diarrhœa were 23 below the average; this disease was proportionally most fatal in Fulham, Shoreditch, Bethnal Green, Poplar, Bermondsey, and Deptford. In conclusion, it may be stated that the aggregate mortality from the principal infectious diseases in London last month was nearly 11 per cent. above the average.

Infant mortality, measured by the proportion of deaths under one year of age to registered births, was equal to 90 per 1000. The lowest rates were recorded in Kensington, Hammersmith, St. Marylebone, Hackney, Greenwich, and Lewisham; and the highest rates in Chelsea, St. Pancras, Finsbury, the City of London, and Southwark.

THE SERVICES.

Royal Army Medical Corps.

Lieutenant-Colonel R. S. F. Henderson has been appointed registrar and secretary at the Royal Victoria Hospital, Netley, vice Lieutenant-Colonel G. E. Twiss. Major G. A. T. Bray has been appointed embarking medical officer at Southampton. Colonel A. T. Sloggett, C.M.G., Principal Medical Officer of the London District, has been appointed president of a board of officers constituted for the purpose of examining candidates for commissions in the Royal Army Medical Corps, on July 24th, in London.

Lieutenant Francis J. Turner to be Captain (dated March 4th, 1907).

Volunteer Corps.

Royal Garrison Artillery (*Volunteers*): 3rd Lancashire: Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel M. J. Fox resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated June 6th, 1907). 6th Lancashire: Surgeon-Lieutenant F. W. Bailey to be Surgeon-Captain (dated June 12th, 1907). 1st Midlothian: William Guthrie Porter to be Surgeon-Lieutenant (dated June 17th, 1907).

Rifle: 2nd Volunteer Battalion the Hampshire Regiment: Herbert George Harris to be Surgeon-Lieutenant (dated June 1st, 1907). 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry: Alexander Macphail to be Surgeon-Lieutenant (dated June 14th, 1907). 3rd Volunteer Battalion the Prince Albert's (Somersetshire Light Infantry): Percy George McReddie (late Surgeon-Lieutenant) to be Second Lieutenant (dated June 4th, 1907). 1st Volunteer Battalion the Royal Welsh Fusiliers: Surgeon-Captain J. E. H. Davies *resigns* his commission (dated June 14th, 1907). 1st Volunteer Battalion the Duke of Cornwall's Light Infantry: Surgeon-Lieutenant K. M. Pardhy resigns his commission (dated June 15th, 1907). 3rd Volunteer Battalion the Welsh Regiment; Surgeon-Lieutenant C. R. White to be Surgeon-Captain (dated June 12th, 1907). 2nd Volunteer Battalion the Manchester Regiment: Surgeon-Captain J. A. K. Renshaw resigns his commission (dated May 24th, 1907). John Alfred Knowles Renshaw (late Surgeon-Captain) to be Captain (dated May 24th, 1907).

The Military Station Hospital, Devonport.

The Director-General of the Army Medical Service (Surgeon-General Sir A. H. Keogh, K.C.B.), and Sir James R. A. Clark, Colonel-in-Chief of the Royal Army Medical Corps (Militia), on July 10th made an inspection of the Royal Army Medical Corps (Militia) under training at the Military Station Hospital, Devonport. After the parade the Director-General, Sir James Clark, and Lieutenant-Colonel J. M. Jones, R.A.M.C., inspected the wards of the hospital.

staff, with the exception of Dr. Bagshawe, was in favour of rescinding the "Membership" qualification, as was the general body of practitioners in the town, who opposed the introduction of another medical man for the sole purpose of filling a hospital post. On July 4th an extraordinary meeting of governors was held at the hospital to consider the motion that in the above rule the word "or" should be substituted fo the word "and." There was a large attendance which was addressed by Mr. Cecil Christopherson who proposed the motion and other members of the hospital staff and governing body who supported it. Dr. Bagshawe, Dr. Norman Moore, and Lieutenant-Colonel Whittle spoke against it, arguing that the hospital would lose some of its status by the proposed alteration. The meeting was, however, thoroughly convinced by the arguments in favour of the change, the chief of which consisted in a citation of the arrangements at similar principal hospitals and its expediency in meeting the local professional conditions. It was agreed, moreover, that the hospital could be most efficiently conducted by medical graduates at present practising in the town. The motion was accordingly carried by a large majority.

COLOTOMY—CONSTIPATION.

To the Editors of THE LANCET.

SIRS,—Would any of your readers kindly suggest drugs or other treatment for a colotomy case (the operation was *not* for malignant disease) where the bowels are obstinately constipated and not responsive to even strong drugs—e.g., two-thirds of a grain each of aloin and jalapin at bed-time. The effect of cascara is uncertain and unsatisfactory and calomel (one or two grains) followed by saline too purgative, producing liquid evacuations only. Dietary with fruits, vegetables, and brown bread is useless for a daily move. What is required is a drug or treatment which will produce daily one or two pultaceous motions before midday. Is it possible to adopt any treatment which would achieve this end? The general health of the patient is fair.

I am, Sirs, yours faithfully,

July 15th, 1907. THE SUFFERER (A MEDICAL MAN).

A GARBAGE MONGER HEAVILY FINED.

Ernest Henry Harrison, a butcher of Holbeach St. John's, Lincolnshire, was recently fined £20 at the Guildhall police court in respect of each of three carcasses of pigs consigned by him to the London Central Meat Market. The evidence of Dr. W. Collingridge was that when he saw the carcasses they were "obviously" unfit for human food, and even the defendant, who swore that he believed them to be sound, admitted that when he sent them he realised that they were not of prime or first-class quality. The alternative of going to prison for a month was given him should he not pay the fines, amounting to £60 with £4 14*s.* 6*d.* costs, inflicted by Alderman Sir George Smallman who was informed before he passed sentence that the defendant had been cautioned several times as to the doubtful quality of meat which he had consigned to the market.

A PLEA FOR VENESECTION.

To the Editors of THE LANCET.

SIRS,—The painful incident, which has just occurred, of a Member's sudden death in the House of Commons tragically draws attention to the reluctance of the medical profession nowadays to practise venesection. Quoting from the papers I learn that "Sir Alfred looked very flushed" and that "a hypodermic injection of ether was made' Without doubt such a patient 80 years ago would have been bled freely, and probably with benefit. The article under "Looking Back" in your journal of June 15th is instructive in comparison

I am, Sirs, yours faithfully,

July 10th, 1907. G. P.

A STUDENT'S COMPLAINT.

To the Editors of THE LANCET.

SIRS,—In these times when the medical student has so much reading to do his labours are added to by many publishers putting books before him which are anything but a comfort to read. They use shiny paper, the type is too close together, is too faint and indistinct. The "thick down strokes and thin up-strokes" kind of letter is distinctly irritating to the sight. Americans and Germans err more than we English but I am afraid the tendency is growing here to imitate their book faults. If your reviewer when noticing books in your columns would condemn all books sent to him which were not printed upon dull paper and with good, *square, heavy* type he would do a great service to not only the reader but to the authors themselves whose labours are often spoilt by the printing and paper of the books they write. Some think that if a large type is used that is sufficient. It is not the *size* but the *shape* of the letter which makes for distinctness. The idea seems to be nowadays to cram as many letters into a *line* as possible.

I am, Sirs, yours faithfully,

July 13th, 1907. SIGHT NORMAL.

⁂ We sympathise with the criticisms of our correspondent, who will find some remarks bearing upon the subject in THE LANCET of Oct. 20th, 1906. The use of shiny paper is rendered necessary by the very general employment of half-tone blocks for illustrations. These are much cheaper and in some cases more satisfactory than the old line blocks, and there is a very considerable advantage to the reader in having the illustrations in the text. It is difficult therefore to suggest a remedy, though every endeavour should be made to use the more legible kinds of type, and in this respect, as our correspondent says, our books compare favourably with foreign publications.—ED. L.

THE COST OF A UNIFORM FOR THE ARMY MEDICAL RESERVE.

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent's query in THE LANCET of June 29th, the articles required are: Khaki breeches and tunic, one pair puttees, six collars for uniform, one pair brown boots with plain toe-caps (heavily nailed), forage cap, and Sam Browne belt. The cost comes to under £10. No sword is required, and to get one is merely wasting £3 5*s*. Officers should take down their civilian evening dress and a lounge suit. If they do not spend much on outside amusements, such as tennis, boating, &c., they will make a clear profit of about £24 on the two months besides having a very good time.

I am, Sirs, yours faithfully,

July 15th, 1907. A. B. C.

SPEED VERSUS COMFORT ON RAILWAYS.

To the Editors of THE LANCET.

SIRS,—Referring to a letter under this heading in THE LANCET of July 6th, signed "An Occasional Traveller," and his reference to my 24 hours' drive at Brooklands, my drive was undertaken for the purpose of making some interesting tests: first, as to whether one person could give the necessary concentration to drive 60 m.p.h. for 24 hours continuously; and secondly, to prove that a British made motor-car could travel at a high rate of speed for a longer time continuously than any other vehicle had ever run during the history of the world. Both these points were proved, and I think it was no disadvantage to the whole British motor industry that the drive was undertaken.

Your correspondent's statement that he could make a motor-car travel a greater distance without a driver is interesting, and I shall be very pleased to lend him a car similar to that which I used if he will undertake the test he suggests he can make forthwith. Personally, I doubt his ability to make good what he suggests he can do.

I am, Sirs, yours faithfully,

New Burlington-street, London, W., July 15th, 1907. S. F. EDGE.

Ormond-street (9.30 A.M).

hich I was able to apply it the presence of fluid might ave been determined beyond reasonable doubt. When roperly checked by test and counter-test the paravertebral iangle is our finest and apparently our only reliable reagent r the detection of small amounts of free fluid at the base of he pleura and also for some estimate as to its quantity. his method of diagnosis is at the same time by far the asiest and the most rapid to carry out. It is, therefore, kely to be regarded in the future not only as important but s often indispensable.

I am, Sirs, yours faithfully,
WILLIAM EWART.

Curzon-street, Mayfair, W., July 14th, 1907.

THE TSETSE FLY.

To the Editors of THE LANCET.

SIRS,—At a time when so much interest is being taken n the tsetse fly it may be of interest to some of your eaders to make known publicly what I have already mentioned to one or two medical friends. About three years go (when I was travelling commissioner here) I asked some ative chiefs if they knew the fly that did harm to their attle. They said they did but that the fly did no damage *nless it had previously bitten a "red" monkey.* By this I hink is meant a "yellow" monkey, not uncommon out here the natives have no names for different shades of colour as e have), and I never saw a "red" monkey. I give this for hat it is worth, but there was no reason why a monkey hould have been mentioned any more than a goat unless the atives thought there was some truth in the statement. Vestwood ("Introduction to Study of Insects") mentions n a footnote that M. Vallot noticed the existence of an astrideous larva in a monkey, and possibly it was a zimb. he matter seems worth looking into at any rate.

I am, Sirs, yours faithfully,
J. WINN SAMPSON, F.R.M.S.,
Police Magistrate.

Calabar, South Nigeria, June 14th, 1907.

THE HAMPSTEAD GENERAL HOSPITAL.

To the Editors of THE LANCET.

SIRS,—In your last issue Mr. A. Craske makes a great deal of hat is obviously an error in the report of my speech. My ssertion was that the income from the invested funds of the orth-West London Hospital was under £200 a year; it is ctually £170.

I am, Sirs, yours faithfully,
E. COLLINGWOOD ANDREWS.

Hampstead, N.W., July 16th, 1907.

HE IMAGINATIVE TEMPER IN SCIENCE.

To the Editors of THE LANCET.

SIRS,—I think homœopaths will have good reason to rumble with your article on the "Imaginative Temper in cience" and to comment on the taste and tact of the riter and also of the Editor in introducing this subject into leading article and making statements about it which its ollowers will be unable to controvert, not because they annot, but because their replies would be boycotted, as this ne will be, by the Editor who places as a motto over one of is columns "Audi alteram partem."

I am, Sirs, your obedient servant,
J. J. G. PRITCHARD.

Dewsbury, July 14th, 1907.

A NIGHT SHELTER FOR WOMEN AND GIRLS.

To the Editors of THE LANCET.

SIRS,—We beg your courtesy for a little space in your aluable journal for a special appeal on behalf of a heap and decent night shelter for women and girls which e are anxious to establish in London. The idea is he outcome of hundreds of sympathetic letters received ince the publication of "The Soul Market" which gave Mrs. Archibald MacKirdy's personal experiences among the poor and outcast. A lady has promised us £1000 if four ther ladies or gentlemen will give or collect like sums.

The plans for the shelter are made on the most economical nd practical lines. It is hoped it will, when built and quipped, be self-supporting. The charges will be 2*d.* to 4*d.* night and this refuge will be the means of helping many a girl and woman back to good citizenship and decent living. We are favoured with Royal sympathy and our committee include the following ladies and gentlemen among others:—The Duchess of St. Albans, Lady Wemyss, Lady Brassey, Lady Evelyn Moreton, Lady Wright, Mrs. Herbert Gladstone, Lord Reay, Lord Curzon, Lord Brassey, Lord Strathcona, Sir W. Wright, Sir Dyce Duckworth, Sir W. S. Gilbert, and the Rev. Arch. Fleming.

Subscriptions may be sent to Lady Brassey, the treasurer of the fund, at 24, Park-lane, London, W.

We are, Sirs, yours very truly,
SYBIL DE V. BRASSEY,
OLIVE CHRISTIAN MACKIRDY.

July 12th, 1907.

THE REFORM OF THE ROYAL NAVY MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—The Lords Commissioners of the Admiralty have just issued an order that naval medical officers are not to receive fees for evidence at coroner's inquests or for performing post-mortem examinations on a coroner's order, and that they are to consider this part of their duty as naval medical officers. I ask you to publish this letter because I think that this order may have been issued before their lordships had been sufficiently well advised upon the matter, and also in order that we may hear through your valuable columns the opinions of some of our brothers in the profession. I have always believed that on taking our diplomas to practise as medical men and becoming registered we were, partly by power of the Charter of the Medical Faculty to which we belonged and partly by right as a registered medical practitioner, entitled to certain privileges and at the same time bound by certain restrictions. The right to demand fees from a coroner I have always looked on as a right conferred by being a registered medical man. Surely, if one class of Government officials are to be debarred from receiving these fees that can only be done by Act of Parliament, which would alter the coroner's law, and at the same time surely it should be made applicable to all paid out of the public purse, whether Admiralty, War Office, Local Government Board, or municipal authority.

I regret to say that there is a feeling of uncertainty in our branch of the profession as to whether you would care to ventilate our grievances in your valuable journal owing to pressure from the medical department of the Admiralty, who are not anxious that candidates for the Service should be deterred from joining when they read what is published. As I am sure that you would not close your valuable journal to any true and sensible grievance I send you this letter. There is a widespread view that it is quite time that the suggested reforms by which many were lately induced to enter the Service should be brought in as there is a great desire for improvement by many, not in the direction of pay, rank, or privileges, but in promotion of efficiency throughout the Service. The open disapproval shown to men who endeavour to improve their general knowledge by working at bacteriology has caused much discontent. The present way of distributing hospital appointments which are so few as to be insufficient to enable every medical officer to obtain one during his whole career in the Service and which could so easily be remedied by shortening the term of office; and in order to avoid long journeys and expense to the department in travelling exchanges could be effected every 12 months with men serving in the port or in the fleet attached to the station. The present system of employment of large numbers of medical officers in the home and reserve fleets which all have reduced crews and most of the home fleet ships having two medical officers. These fleets, the home and reserve, have not sufficient work for one man for three ships. It certainly shows the kindness and generosity of the Admiralty in keeping the officers on full pay, but I for one would much rather have efficiency than idleness, as once appointed to one of these ships one has to remain on board daily from 9 A.M. to 1.30 and most ships until 3.30, although there may not be one man sick and there is always one ship flying a medical guard flag which signifies an officer on board all day for emergency. There are many who suggest that in the case of these medical officers they should, after visiting their ship in order to see the sick, be appointed to the hospital as medical or surgical registrars in order to keep

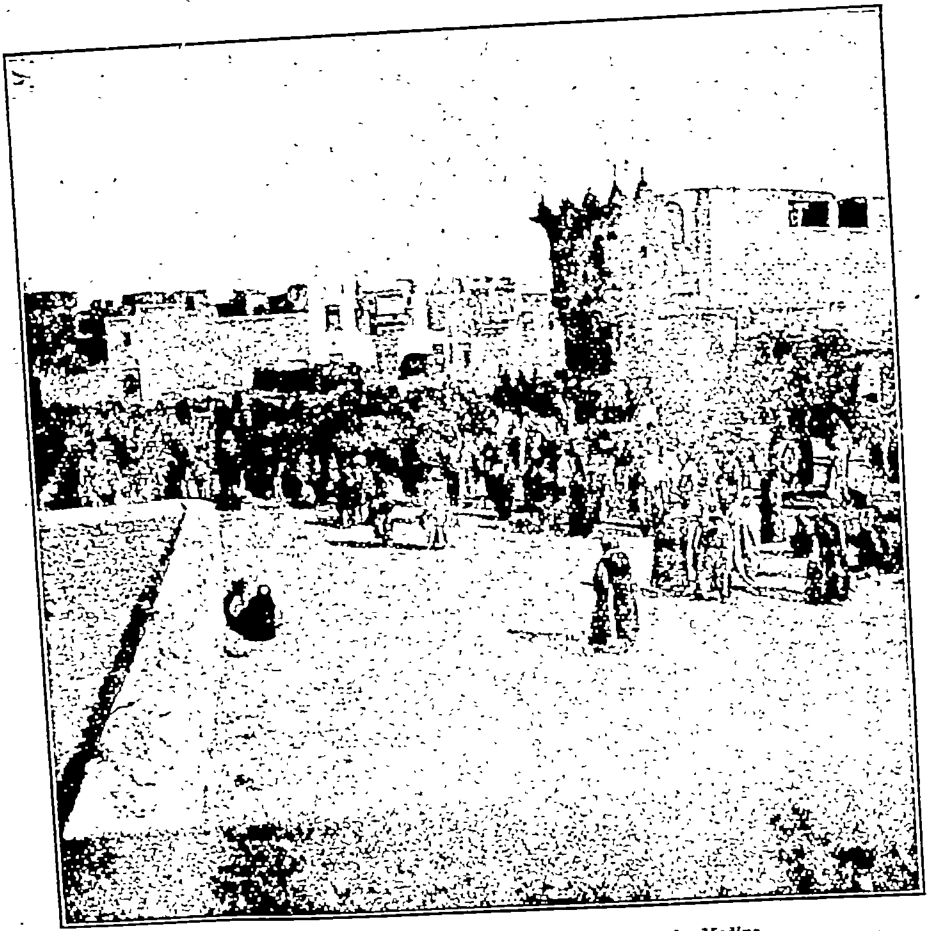
Fig. 38.

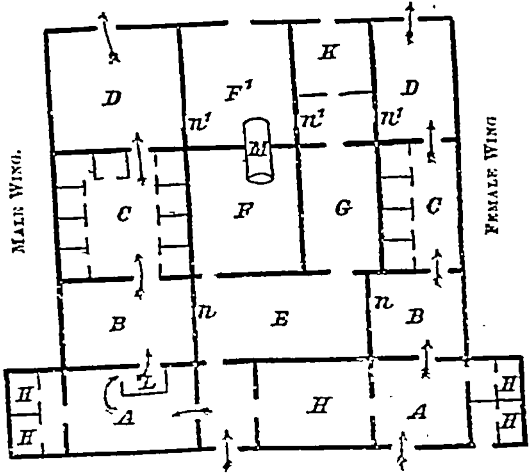


Yanbo: the first caravan of the season preparing to start for Medina.

y are a ruined stone building and some tents occupied y Arab fishermen. This island would be admirably fitted r the site for the disinfecting station but for one fatal rawback—it is surrounded by shallows and reefs for nearly alf a mile in all directions; these are more or less dry at uite low tide but are for most of the 24 hours covered with foot or two of water. In order to land on the island we ere compelled to wade ashore for a distance of several hundreds yards. From subsequent exact measurements it was found that were it decided to build here a landing pier the extremity of which could be approached by boats at all states of the tide it would need to be 600 metres long. Hobsa presents almost equal disadvantages; it would be necessary either to raise its level artificially, so that its surface should be above water at all states of the tide, or to put up the building on piles; in either case a jetty of some length would be required. The architect who accompanied me to Yanbo estimated the cost of the pavilion and jetty at Abbasieh at about £T 2900 and at Hobsa at about £T.2300.

In view of the difficulty in finding a suitable site for a building on land the Constantinople Board of Health is now considering the possibility of having a floating disinfection station at Yanbo. The board already possesses one in the Bosphorus. It is called the *Burhanneddin* and is a floating structure, half lighter, half ship, upon which there is a small disinfecting pavilion containing one modern disinfecting stove. It was hoped that it might be possible to send this to Yanbo and it has been thoroughly examined by a committee of experts with that view. Unfortunately, however, they report that the *Burhanneddin* is not in a condition to be towed over the long distance that separates Yanbo from Constantinople and requires, indeed, serious repairs if it is to continue to be employed on the Bosphorus. If, therefore, Yanbo is to have a floating pavilion it will be necessary to build one specially for that port. Steps to that end are now being taken; plans and estimates have been asked for, and a definite decision on the matter may be expected very shortly.

Plan VI.



Type plan of small disinfecting pavilion as adopted in certain Turkish ports. Scale 1/200. A, A, Waiting rooms. B, B, Undressing rooms. C, C, Douche baths. D, D, Dressing rooms. E, Room for sorting effects. F, Store room ("contaminated"). F', Store room ("clean"). G, Room for chemical disinfection. H, Room for employee. K, Store-room for disinfectants. L, Doctor's cabinet for medical inspection of pilgrims. M, Steam disinfecting stove. At n, n the pilgrims' clothes are passed by a turnstile from the undressing rooms to the store room ("contaminated" side) and at n', n' they are returned, after disinfection, from the store room ("clean" side) to the dressing rooms.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Armstrong College, Newcastle-on-Tyne, Secretary of; Messrs. T. R. Annan and Sons, Glasgow; Mr. W. Innes Addison, Glasgow.

labour. It may be feared, however, that the majority of the tramps are only waiting to resume their summer tour as soon as the skies are propitious.

Manchester Water-supply.

Manchester is a great consumer of water and the chairman of the waterworks committee feels it his duty from time to time to speak against waste and to draw attention to the prospective insufficiency of the supply. For some time, however, there has been too great a supply for the Longdendale reservoirs and during three days of last week a total of no less than 126,000,000 gallons were run to waste. The quantity that has to be run into the river daily to supply the mills lower down is only 14,000,000 gallons. It was reported on July 11th that there was a sufficient supply for 133 days with a daily rate of consumption of 40,000,000 gallons. It is a curious coincidence that on Jan. 1st both of this year and of last year the supply was sufficient for the same number of days. The daily consumption, however, was calculated on 36 000,000 gallons instead of on 40,000,000 as now.

July 15th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

University of Liverpool: Semi-jubilee Celebrations; Graduation Ceremony.

THE three days' programme of social functions organised in celebration of the twenty-fifth anniversary of University College, now the University of Liverpool, was inaugurated on July 11th by a reception at the University, which was attended by about 4000 guests. The arrangements were admirably planned and carried out, conducing to the enjoyment of the visitors. The entrance hall of the Victoria building, the archway of the medical school, and the entrance to the zoology building were used simultaneously for the reception of the guests, who were welcomed by Mr. E. K. Muspratt (Pro-Chancellor and chairman of the Council), Vice-Chancellor A. W. W. Dale, and by the treasurer (Mr. Hugh Rathbone). Refreshments were served in various parts of the building and there was music in the quadrangle by the Liverpool Constabulary Band and in the Arts Theatre and Zoology Museum by the Ross ladies' orchestra. Interesting scientific lectures and experiments proved most attractive and the exhibits were conveniently placed for easy inspection. Academic dress was worn by the graduates. The scene was a most animated one and the reception was one of the most interesting ever held in Liverpool. In continuance of the celebrations the Lord Mayor held a reception at the town hall on July 12th and in the evening of the same day there was a students' ball. But the most important function was the University Association's dinner held at the Adelphi Hotel on July 12th, over which Vice-Chancellor Dale presided. The company included the Lord Mayor of Liverpool, the Lord Bishop of Liverpool, Sir Oliver Lodge, the Rev. Dr. Rendall, the first Principal of University College, Liverpool (now head master of Charterhouse School), Professor Bradley, the Master of Magdalene College, Cambridge, Professor W. Ostwald (Leipsic), Sir Henry E. Roscoe, Professor W. Osler, Sir John Murray, Sir William Ramsay, Professor A. R. Forsyth, and Sir John Brunner, Bart., M.P. Sir Oliver Lodge proposed the toast of "The University" and gave an interesting account of the foundation of University College (now the University of Liverpool) of which he was professor of physics for 19 years. Professor MacCunn, in responding, said that he would not attempt to estimate what the University of Liverpool owed to the scholarly devotion of Rendall, the insight of Bradley, the brilliant gifts of Forsyth, the eloquence and wit of Raleigh, the indomitable scientific fidelity and enterprise of Gotch, and not least to the large-hearted scientific genius of Sir Oliver Lodge. The Vice-Chancellor proposed "The Guests" in a humorous speech, which was replied to by Sir Henry Roscoe, Professor Forsyth, and Professor Osler.—The graduation ceremony, held at St. George's Hall on July 13th, was an occasion of special interest and importance; several honorary degrees were conferred by the Chancellor, the Earl of Derby, on men distinguished in arts and science, among whom for the degree of D.Sc. were Professor Francis Gotch, Principal Sir Oliver Lodge, Professor Osler, Professor Forsyth, Sir John Murray, Professor Ostwald, Sir William Ramsay, and Sir Henry Roscoe. The degree of LL.D. was conferred on Sir Edward Lawrence and Mr. Muspratt (both Pro-Chancellors of the University) in acknowledgment of their pioneer work in and for the University. At a luncheon which followed the graduation ceremony an oil portrait of Mr. Muspratt, which had been subscribed for by members of the University club, was formally presented to the club, and in the afternoon a garden party was given by Sir John Brunner in his charming grounds at Druid's Cross, Allerton. In the evening the students wound up the commemoration festivities with a supper at the Yamen Café. Altogether the occasion was a memorable one.

Liverpool School of Tropical Medicine.

Sir Alfred Jones presided at a dinner given on July 15th in the University Club, Liverpool, for the purpose of bidding farewell to Dr. Barrett and Dr. Yorke, members of the Black Water Fever Expedition, who are going out to Africa, and to Dr. J. L. Todd, late director of the Tropical Research Laboratories at Runcorn, who is returning to Canada. Sir Rubert W. Boyce, in proposing Dr. Todd's health, said that coming from Canada he had been willing to work in every part of our Empire, and while giving his time and talents he had also contributed something like £200 per annum to the Tropical School, and, more particularly, to the institution at Runcorn. Sir Alfred Jones having also spoken, Dr. Todd, in response, said that very little gratitude had been displayed for the work of Dr. Dutton who died whilst engaged in research work, only one-quarter of the sum required to establish a professorship in his honour having been collected. The Bishop of Liverpool proposed success to the "Black Water Fever Expedition." Professor Ronald Ross supported the toast, which was acknowledged by Dr. Barrett and Dr. Yorke. On the motion of the American Consul, the toast of "The Study of Tropical Medicine" was honoured, and was responded to by Colonel D. Bruce, R.A.M.C., who alluded to the recent successful work in connexion with Mediterranean fever.

July 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Prevention of Cruelty to Children.

THE Glasgow district committee of the National Society for the Prevention of Cruelty to Children reports that during 1906 the number of cases of alleged cruelty dealt with by the inspectors was 1605, being an increase of 78 on the previous year. The number of children affected was 4679, as against 4411 in 1905. The number of children received and cared for in the shelter was 549. The ordinary income was £1281 and the ordinary expenditure £1271. Legacies amounted to £323, and £2745 were received in response to a special appeal to the public.

Action against a Druggist.

In the Court of Session last week a pharmaceutical chemist in business in Dundee was sued for £500 damages in respect of injuries said to have been sustained by a girl, aged five years. The child was suffering from ringworm and it was alleged that the druggist advised the application of butter of antimony to the scalp and supplied a bottle the contents of which were applied, with the result that the girl lost all her hair and her health was injured. Lord Johnston assoilzied the defender with expenses. He stated that he was satisfied that the defender warned the father of the child that he had no personal knowledge of the drug being used for the purpose in question and that he warned him that it must be applied carefully and sparingly.

Medical Appointments under Govan School Board.

As a result of a conference with Dr. W. Leslie Mackenzie of the Local Government Board in May the Govan parish school board has appointed ten medical officers at a salary of £50 each per annum to assist in the work of medically superintending the children. The new officers are also to advise the board as to the ventilating, heating, lighting, and cleanliness of the schools and to report any insanitary conditions discovered. By means of lectures, demonstrations, or otherwise the teachers are to be instructed in the method of recognising the common ailments and defects of school children, in the practice of first aid for school accidents, in the general hygiene of the school and the class-room, and in the physiological principles that underlie physical training. There were 66 applicants for the posts as advertised.

proposals dealt only with infected persons and infected goods and did not include Fiocchetto's recommendation that arsenic should be prepared for the rats after the cats, dogs, fowls, and pigeons in an infected house were killed. It is obvious that if the lower animals, and particularly rats, suffer from plague and spread the infection to men, measures directed solely to infected persons and infected goods will not stay an epidemic. The very slow recognition of this fact has contributed more than any other cause to the spread of plague once the infection has been imported into a new locality and has become established there.

For many years before plague appeared in India my thoughts had been directed to the possibility of preventing disease in man by dealing with the allied disease in animals before it reached man. It was partly with this view that I had carried on for years researches as to the relationship of small-pox in man with certain diseases in animals. When several cases of plague occurred in Calcutta and rats were dying in several houses in a particular quarter of the town an opportunity came in an unexpected manner of putting this view into practice, for it had been observed in Bombay that the mortality of rats preceded plague mortality in man. Steps were accordingly taken to have the rats destroyed in the few houses in which they were observed to be dying with the object of preventing the spread of the disease. The measure met with success and the sickness and mortality among rats were arrested. I left Calcutta in 1897 and it was not until April of 1898 that rats were found again to be dying in the sheds connected with the shipping and with the railways, evidently a fresh importation; and with the mortality came the first outbreak of plague in Calcutta.

In Cape Town, after much delay and experimenting, large quantities of Danysz's virus were used with the object of destroying rats in infected quarters, and it is remarkable that no recrudescence of plague has ever occurred in this town. In Hong-Kong a similar policy of dealing with the dissemination of the disease by rats was carried out and with comparative success, notwithstanding continual importation of the disease from China. Even this measure has its limits and unless directed with intelligence it is not likely to be successful. It is impossible to destroy all rats in a country and any measure having in view this object is destined to fail. General destruction of rats is good in itself and if the inhabitants of a town or village can be induced to join in a general campaign against rats it is a matter for congratulation. The main point, however, is to deal with the infected rats and for this it is necessary to provide an agency to ascertain where they are and to concentrate energy on infected localities.

PREVENTIVE MEASURES ADOPTED IN INDIA.

With reference to the plague in India the fullest recognition and credit must be accorded to the Government of India for its energetic efforts to prevent the spread of the disease with the agency at its disposal. There can be no question regarding the anxious and strenuous efforts at first made to check and to control the disease. The Government of India did its utmost to encourage the Government of Bombay to pursue an active policy in combating the plague and Bombay did its best. Very large sums were spent for this purpose amounting to at least £500,000 sterling from 1897 to 1900, and another £300,000 for the protection of the other provinces. But the measures were based, with few exceptions, on the view that plague is disseminated wholly by infected persons and infected clothing.

The failure which followed these measures in a country where the sanitary organisation was small and ineffective and where the habits and dwellings of the people favoured the spread of the disease was facilitated by other circumstances. These were the apathetic attitude of the people; the suspicions and alarms aroused by inspection of huts and houses; the opposition, sometimes merging into open hostility, to the removal of patients from their houses; and then, as the disease increased, the panic and flight that followed, with the scattering of the infection far and wide. The difficulties thus met with were immense and a time arrived when it appeared to the authorities that the continuance of active measures for the prevention of the disease was not only hopeless but would raise trouble by exciting generally the hostility of the usually docile and peaceful inhabitants. A general relaxation of measures was accordingly encouraged and the adoption of plague measures was left to the option of the people themselves. In thus avoiding Scylla the authorities do not appear to have been aware of Charybdis. The plague, unchecked, and taking no heed of politics, has gradually shot ahead. Year after year it is gaining ground and the mortality is now producing just those results which were feared would arise from a policy of activity. The disorders and excitability of the inhabitants of the Punjab have come to most people as a shock and a surprise, but they are what history teaches to be inevitable where whole families are swept away and where the people of a country are dying in immense numbers.

The result of a relaxation of efforts proved in the case of the Punjab most disastrous and this has been the case also in other parts of India. For instance, in Berar, a province of nearly 3,000,000 of people, plague was kept well under control for six years. There was no quarantine but notification and surveillance of people coming from infected villages to healthy places and the immediate adoption of preventive measures when a case of plague occurred consisting mostly of evacuation of the infected house and camping out on the outskirts of the village or town. The policy met with remarkable success, notwithstanding constant importation of disease from the Bombay Presidency, Central Provinces, and Hyderabad State, and it was accepted by the people in good spirit so long as the system was believed in by the authorities. But latterly the measures were considered irksome and accordingly they were relaxed. The next season the disease began to spread unchecked and Khamgaon, with a population of 26,000, lost 5000 of its inhabitants in 12 months, and by the end of 1903 and the beginning of 1904 nearly the whole of the province of Berar was infected. In many of the villages the villagers adopted on their own initiative precautions—i.e., vacating their village and camping out at once on the first appearance of a case of plague, or of dead rats, and so escaped an epidemic, while in other villages the villagers were too ignorant or too lazy to take the initiative and adopt precautions and camp out on the first appearance of plague. These almost invariably suffered severely.

There were practically no precautions in force in the city of Nagpur against plague when the second epidemic of plague broke out there in 1903–04 and in five months from November to March there was a mortality of 15,000 in a population of 130,000. Many of the inhabitants took the initiative, vacating the city and camping out, and they escaped, the mortality being among those who remained in the city and who did not vacate their houses.

During the whole ten years one presidency stands out conspicuously as having steadfastly pursued an active policy and of not leaving preventive measures to the option of the people, and this is Madras. The local Government placed full reliance on its experienced sanitary commissioner and its confidence has been amply justified. Under the strong and able direction and administration of Colonel King, I.M.S., assisted with very inferior material as a staff, the plague has been kept under control, notwithstanding the fact that large numbers of infected persons are constantly passing into the Presidency from the neighbouring States.

IS IT POSSIBLE TO DEAL WITH PLAGUE AS IT NOW EXISTS IN INDIA?

Seeing that plague has reached the proportions it has now attained in India the question arises, Are there any measures likely to be useful in checking the epidemic which, while effective against the disease, are applicable to Hindus and Mahomedans and their mode of life? The answer is yes, but in considering this question the sanitary condition of India and the habits, prejudices, and religious scruples of the people have to be recognised. The sanitary conditions of India, however deplorable they are, have to be taken as they exist. They are similar to those in Europe in the fifteenth century. It is not possible when an epidemic prevails to transform a town or a country into a condition which will supply it with light and well-ventilated houses and which will render it free from rats, fleas, and other agents which play a part in the spread of the disease. Measures which may be desirable but which are impossible have to be distinguished from those that are possible. Under the impossible may be grouped any attempt suddenly to change the thoughts and habits of the people or the condition of their dwellings, or their dislike and hostility to wholesale removal of their sick to hospitals, or any measures based on the supposition that the communities in India can defend themselves against plague without the intervention of the Government.

notified to the Registrar-General, as compared with six during the previous week. Of 72 cases in Purdysburn Fever Hospital, 35 were suffering from "spotted" fever and one death only occurred from that disease during the week. The general death-rate for the week ended July 6th was 20·3, which is very high for this time of year.—The Belfast Health Commission resumed its sittings on July 15th, when, after three officials of the water board (the consulting engineer, engineer, and superintendent of works) and a builder, who was examined as to inspection of a conduit, had given evidence, Mr. A. H. Bates, K.C., gave a long address on the evidence put forward in reference to the water-supply of the city, setting himself to face the important issue as to how far the water system was responsible for the typhoid fever outbreaks in Belfast. He said that the presence of typhoid fever was only part of the health problem in Belfast, the striking fact being the general high death-rate. He showed that typhoid fever was both endemic and epidemic in Belfast and as endemic was startlingly high in its incidence, and yet there was no suggestion that it was due to the water-supply. As to the epidemic form of typhoid fever being due to the water-supply, he maintained that the theory that two water catchment areas (Stoneyford and Woodburn) 20 miles apart, with different physical conditions, different histories in point of health, and different features, could recurrently, periodically, and concurrently be affected in the same way was inconceivable. Proceeding, Mr. Bates dealt fully with Professor J. Lorrain Smith's evidence and report and quoted from him that in a certain area in Belfast (occupied by the artisan classes) the smoke test showed that 37 per cent. of the drains were defective, and in another area 73 per cent. of the drains were wrong, the point being that where typhoid fever was found in such areas as these sanitary defects at once came into operation for the purpose of spreading the disease. He concluded by speaking highly of the water board and deprecated any suggestion of extending the Mourne scheme faster in its development than was contemplated by the original promoters. Mr. H. A. Cutler, city surveyor and engineer, was then examined as to the Belfast main drainage scheme.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Pellagra and Insanity among Arabs.

AT a meeting of the Academy of Medicine held on June 25th M. Marie said that an examination of insane Arabs suffering from pellagra in the Abassech Asylum showed that genuine pellagra was almost constant among them just as among the population from which they were derived; they were therefore pellagrous persons who had become insane. Some mental disorders following pellagra owed their origin to it, and on that account presented typical psychological characteristics associated with the physical symptoms of pellagra. Certain paralytic forms of insanity occurred in pellagrous individuals and confirmed the opinion of Baillarger who maintained that pellagrous paralysis might assume a form clinically and pathologically identical with general paralysis of the insane. The diseases were, however, not the same and M. Marie considered that general paralysis of the insane was a syphilitic manifestation. The two forms might be combined—that is to say, cases were known in which Arabs suffering from general paralysis were both syphilitic and pellagrous.

The Action of Salts of Lime on the Heart.

Some experiments described by M. Loeper and M. Boveri at a meeting of the Society of Biology held on June 22nd served to confirm the well-known opinion that salts of lime exercised an exciting effect on the cardiac muscle. These observers have noticed in the human subject an increase of the arterial pressure and a slowing of the heart beats after the ingestion of chloride of calcium. On the other hand, they found a notable increase of the weight of the heart in rabbits to which there had been given for a month doses of one or two grammes of chloride of calcium and two, four, or even eight grammes of carbonate or phosphate of calcium. They, moreover, obtained evidence that the hypertrophy of the heart arising in this way was accompanied by an accumulation of calcium salts in the cardiac substance.

Lead Poisoning.

At a meeting of the Academy of Medicine held on July 2nd M. Meillère presented an important communication on lead poisoning regarded from the chemical point of view. The conclusions arrived at from this aspect were very similar to those which were formed on purely clinical grounds. It was shown that lead was a poison attacking specially in the nervous system the grey substance of various centres, and in the sanguineous system both the blood corpuscles and the organs or structures in which they originated—namely, the liver, the spleen, and the bone marrow. By its long retention in the affected tissues and the slowness of its elimination the lead interfered with nutrition, disturbed the normal relations of the mineral constituents of the body, and brought about a kind of premature senility. These disastrous effects attained their greatest development in degenerates of all kinds whose constitution rendered them unusually susceptible to the poisonous effects of lead. M. Meillère has investigated the elimination of lead by the hair of various parts of the body and by the nails. He also discussed the question of the normal presence of lead in the tissues and concluded with a description of the best methods of conducting researches on the toxicology of lead.

Treatment of Cancer of the Stomach.

At a meeting of the Société de l'Internat des Hôpitaux de Paris held on June 27th M. Doyen showed some cases of cancer of the stomach treated by his method. The total number of his successful cases is now 16. Some were treated as soon as the first definite symptoms appeared, whilst others were inoperable. As a result of the treatment the vomiting and the cachectic colour of the skin disappeared and the appetite returned. Among the 16 patients pylorectomy was performed in one case and simple gastro-enterostomy in four cases; the remaining 11 patients were not operated on. It was mentioned that four patients were treated respectively five years ago, four years ago, three years ago, and two and a half years ago. In two cancerous patients a biliary obstruction also disappeared. M. Doyen has also during the last few months successfully treated cases of cancer of the œsophagus, cancer of the rectum, cancer of the larynx, and *cancer en cuirasse* of the two breasts with peritoneal invasion. He attaches great importance to the early use of vaccine.

Obituary.

Professor Grancher, who on account of his health has for many years past been compelled to winter in the South at Cambo, died in Paris on July 13th. He was born in 1850. Having entered the medical profession he presented for his doctor's degree a thesis entitled, "L'Unité de la Phthisie." Since that time he chiefly concerned himself with researches into tuberculosis. He was one of the first to make laboratory experiments upon anti-tuberculous "vaccination," and he also for some time worked with Pasteur. In 1892 he became a member of the Academy of Medicine. His later years were devoted to the service of a society founded by himself for the protection of children from tuberculosis (*préservation familiale contre la tuberculose*).

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Garibaldi and "Claims to Priority."

THE unselfishness of the Liberator, was, morally speaking, his most distinctive feature, fraught with lessons to his compatriots and to his contemporaries of all nationalities, not only in the military sphere but in every field of coöperative endeavour. The "fruits of victory," the "spoils of war," the "glory" that awaits success had no fascination, no meaning for him. In 1860, when under the walls of Capua, to which he was laying siege, he was importuned by Graziotti, one of his officers, in these words: "General, let me launch a couple of shells at the citadel and it will surrender immediately. To-morrow the Piedmontese army will come and they, too, will bombard the stronghold and tell the world that they have taken it." "Let them say it," answered the general; "we have not come here for glory." A characteristic remark! At Montevideo, after the victory of the Salto, he refused from the struggling Commonwealth every recompense or honour, declining even the proffered rank of not confined themselves to these classes, for the Brahmins have also suffered heavily. Large numbers of women and girls in all classes have been left husbandless and young girls betrothed to young men have been made widows with no possibility of remarriage but with all the drawbacks before them of an Indian widow's life. The devastation produced by plague is not a mere question of so many deaths but the sickness and suffering, the despair and the losses, and the evils entailed thereby engender other evils and a discontent which it is difficult for any Government to meet, however anxious it may be for the welfare of its subjects.

I shall now pass on to the measures which I found in force to deal with this great epidemic. The staff consisted of Dr. Satpute and three hospital assistants. One of these hospital assistants was employed in disinfecting houses so far as possible and the other two in treating patients at their own homes. Good work had been done so far as such a staff was able to do it but it was a microscopic staff attempting a herculean work: 1200 people had been inoculated since the middle of July—i.e., in the course of two months. The Government granted 8 annas to all the servants who were inoculated and the municipality 4 annas to others. Some 2000 persons had gone out to the municipal health camps which were available for those whose income was less than 16 rupees a month. Some 7000 people had made health camps for themselves on the outskirts of the town. The rich had gone to their country houses and the remainder of the 60,000 had taken to flight. About 20 out of every 100 patients were removed to the plague hospital. 2½ annas daily, with medicine, milk, sago, and sugar, were supplied by the municipality to the poorer patients attended by the two municipal medical officers. Four native medical men were fighting against an epidemic which had reached the proportions I have stated and their energies were devoted mainly to tending the sick. With a trained service available Poona could have immediately had the necessary assistance to deal effectively with this epidemic.

FOR COMBATING PLAGUE IN INDIA AN ORGANISED STAFF AND A POLICY ARE THE FIRST ESSENTIALS REQUIRED.

Having considered what is impossible and useless to attempt in India I now come to that which is possible. But before doing so it is necessary to look at the financial position of India, for if there are no funds available to provide money and an adequate machinery then the only policy possible is that which has already been followed with the results mentioned. In any circumstances, when the plague becomes a terror to everyone it is questionable whether attributing the scourge to the hand of God, as was recently done by the Under Secretary of State for India, is the best way out of the difficulty. Evidently Lord Palmerston's rebuke to those who wished to place the blame of the cholera epidemic in England on Providence was forgotten.

As regards finances, with the exception of 1896-97, when nearly £1,500,000 were spent on famine relief, and 1897-98, when over £3,250,000 were similarly spent, there have been large surpluses in the revenues of India during the past ten years. This is not due to money not being devoted to famine purposes, for in 1899-1900 over £2,000,000 were spent in this direction and £1,000,000 have been annually devoted to famine purposes and famine insurance ever since. The figures indicate the liberal, magnificent, and statesmanlike policy carried out in India for the prevention and mitigation of the effects of famine. Hundreds of thousands of lives have in this way been saved.

A similar policy is required in regard to plague prevention, which destroys more lives even than famine. Since 1896 some £17,000,000 sterling have been spent on famine, nearly £1,500,000 on plague, and in spite of this there have been surpluses amounting in the same number of years to over £20,000,000. Of the £1,500,000 spent on plague since 1896 a little over £200,000 have been spent on the Punjab where nearly 2,000,000 people have died. During the years 1905-06, which is the last account available, the Imperial Government of India spent for the plague in the Punjab the sum of £2423 and in Madras £34,603.

The following are the annual amounts spent by the Government on plague in the Punjab and the Madras Presidency since 1897:—

	Punjab.	Madras Presidency.
	£	£
1897-98 ...	8,877 ...	... 4,234
1893-99 ...	19,674 ...	... 46,382
1899-1900...	11,560 ...	... 39,319
1900-01 ...	21,045 ...	... 13,880
1901-02 ...	34,632 ...	... 14,592
1902-03 ...	51,772 ...	... 24,591
1903-04 ...	28,980 ...	... 37,277
1904-05 ...	19,526 ...	... 52,128
1905-06 ...	2,423 ...	... 34,603

With money available there is no difficulty in providing a special plague organisation for plague work and for supplying it with the requisite material for carrying on an anti-plague campaign. Such a campaign must, however, be based on a well-defined, fixed, and steadfast policy which shall be well known and readily applied. This would not debar modifications being made in the application of the measures according to local circumstances and the discoveries of science. The principles guiding such a policy would be first the discarding of measures which are inapplicable to India and which on that account are bound to be unsuccessful; also of measures which, though useful from a health point of view, have no influence on plague; and, secondly, the steady application of measures known to be of value; for instance, the passport system, inoculation, evacuation, destruction of rats in infected localities, and the disinfection in its widest sense of infected houses. These have all been recommended and tried more or less at one time or another in several places—i.e., locally; but their success depends on their adoption in every province and on the agency and regularity and thoroughness with which they are carried out. With a special organisation provided such measures are possible and without it the attempt to deal with the epidemic is hopeless.

MEASURES TO PROTECT HEALTHY DISTRICTS.

Differentiation is required in the treatment of areas in which the disease is endemic and in which it is not. Healthy districts should in every circumstance be kept free from plague. This can be effected as it has been done in the Madras Presidency by a passport system and surveillance and immediate action on the occurrence of a case of plague. No relaxation on any account should be allowed. This should be an imperial policy admitting of no modifications. It is to the interest of the locality concerned and to the interests of adjoining localities which are unaffected. Examples have already been given of the alarming results following relaxation in this respect. A careful inspection of crates filled with goods from infected localities should also be arranged for in order that any dead or sick rats may be immediately discovered and disposed of in a safe manner and the contaminated portion of the goods disinfected; for the same reason an inspection of fodder and loads of grain from infected localities is necessary. The warehouses attached to railways and docks require to be specially watched, also granaries, stables, slaughter-houses, and markets, where rats from infected localities are likely to be imported and spread infection among indigenous rats or where contaminated goods infect healthy rats.

MEASURES IN INFECTED LOCALITIES.

With regard to infected areas the only measures on a large scale available are inoculation, evacuation, and disinfection of infected houses and destruction of rats. Of these inoculation is by far the most powerful and effective. The feasibility of inoculation in the infected districts and houses, if a suitable agency is employed, is demonstrated by the success of the inoculation campaign undertaken in 1902 in a portion of the Punjab. The scheme as originally planned was to inoculate 7,000,000 of the people at a cost of a little over £50,000. It was a splendid conception and if the time and planning devoted to its realisation had been more liberal and less hurried the organisation would have been on a larger and more complete scale and more adequate for the occasion. Half a million of people, however, were inoculated and an investigation carried out by the Government of the Punjab showed that the mortality from plague among the inoculated was reduced to one-twelfth of that which occurred among the non-inoculated, so that it is estimated that 13,000 lives were saved by inoculation during that season.

The Mulkowal accident which occurred at the commencement of the campaign unfortunately shook the confidence of the Government in the prophylactic supplied and, as I have shown, the laboratory was wrongly held responsible for an accident which was actually due to defective organisation which admitted of faulty technique in the application of the prophylactic at the time of the inoculations. The people themselves, however, appear to have understood that the tetanus was an unfortunate accident and were not in the least deterred from availing themselves of the inoculations any more than people are deterred from railway travelling because an express train has met with an accident. This is apparent from the fact that whereas before the accident happened over 100,000 persons came forward to be inoculated, during the season subsequent to the accident nearly 400,000 were inoculated. Major S. Browning Smith of the was that there is no longer any question as to the specific field of action of the Roentgen ray in all forms of acne, lupus, eczema, psoriasis, pruritus, tinea, sycosis, mycosis fungoides, senile keratosis, venereal condylomata, and hyperidrosis. Among the skin diseases that may be classed as erratic are pigmented vascular nævi, hypertrichosis, and acne rosacea. Of the first mentioned, about 18 per cent. are cured and about 28 per cent. are improved. It was stated that 80 cases of epithelioma involving the skin only were treated with no recurrence. When the tumour is situated at a mucocutaneous junction it is well to have the glands removed after a period of quiescence has been brought about by the x rays. Justus followed this method in several cases with no recurrence after two years. He considered the Roentgen rays sufficient treatment in the great majority of cases. The knife should be used only in cases where the tumour is situated favourably for radical removal. In cases having the characteristic odour he invariably anæsthetises the surface and by means of the galvanic current drives into the tissue for a prolonged period of time zinc and mercury ions, following this medication with the Roentgen rays after the separation of the slough. 18 cases of carcinoma treated vigorously with the Roentgen rays were cured. In 14 cases the tumours and enlarged glands disappeared completely; in four they ceased to grow. He considered that all primary cases should be treated with the rays, excluding the knife. He does not believe in the existence of a case of sarcoma that cannot be markedly benefited by a prolonged mild radiation from an old hard tube, well coated with aluminium, the thickness depending on the individual circumstances existing in each case.

Communicability of Cancer.

At the Cancer Congress held lately in Budapest Dr. Kaczvinsky read a paper on the Communicability of Cancer. He is of the opinion that cancer is a communicable disease. The reasons for this are, first, its great increase in modern times; the fact that cancer is most frequent where population is densest—that, for instance, it is more common in direct ratio to the density of the population in the poorer districts in Budapest than in any other; that it seems to follow certain watercourses; that it becomes connected with houses; and that so many cases that are seen by surgeons can be readily traced to possibilities of communication. For instance, it is not unusual to find cancer occurring in those who are closely associated with one another. Dr. Kaczvinsky has recently seen a cancer of the tongue in a workman who had been with another workman suffering from the same disease. Some observers have seen it in two brothers who were living in intimate association, in a brother and sister where one had nursed the other, and in a wife and husband who had been very much together.

July 10th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Cholera in Calcutta.

A RECENT report by Dr. T. Frederick Pearse supplies a striking instance of the conveyance of cholera by unfiltered river water. In an analysis of 1340 deaths from cholera in Calcutta during the first three months of the present year it was found that only 7·66 per cent. of the total cholera deaths occurred among Mahomedans, although this community forms 28 per cent. of the total population. On the other hand, the incidence among Hindus was correspondingly severe—the Hindu deaths amounting to 91·9 per cent. of the total, while the Hindu population is only 66 per cent. of the total. The number of Hindu females attacked was remarkably high in proportion to their numbers—no less than 40 per cent. of the deaths occurring amongst them, while in numbers they form only 23 per cent. of the total population. Hindu males were attacked at the rate of 51·3 per cent. of the total, while in numbers they only constitute 43 per cent. of the total population. In a list of 16 specified castes the greatest sufferers were the Khandait, Brahmin, Teli, Boisnab, Bania, and Shaha castes. A table annexed to the report shows a great preponderance of cholera deaths in the municipal wards which border either on the river or on the branch of it called Tolly's Nullah.

The Calcutta Hospitals.

The annual report concerning the Calcutta hospitals has just been issued. They are 17 in number and received 23,136 in-door patients and gave relief to 271,078 out-patients during the past year. This is a considerable increase, but some two or three do not seem to have progressed. No less than 44,746 cases were treated for malaria and 212 cases of opium poisoning were attended to. Of the total of patients 58·33 per cent. were men, 19·78 per cent. women, and 21·89 per cent. children. The total income of these institutions was Rs.14,48,153, of which the Government contributes Rs.9,34,743, or 68 per cent. The paying patients brought in Rs.98,149, but the public subscriptions amounted to only Rs.41,910 (less than £3000). Considering how largely the natives of India benefit by these institutions the public subscriptions are very meagre. The expenses of up-keep amount to about 10 lakhs (roughly £67,000). Some of the hospitals have been vastly improved and brought into line with modern requirements.

The Madras Medical College.

In his report on the work of the Madras Medical College during the session 1906–07 Lieutenant-Colonel W. B. Browning, I.M.S., C.I.E., the principal, states that there were 327 students on the rolls during the year, showing a decrease of 32, as compared with 359 in the previous year. Of the 327 students, 206 (of whom nine were females) attended the College department, where 103 studied for the qualifications of M.B. and C.M., and 69 for those of L.M.S. The results in the final M.B. and C.M. examinations were much better this year than in the two previous years, there being 60 per cent. of passes, as compared with 46 per cent. in the session 1905–06. In the apothecary department there were 66 students. The 55 remaining students of the total 327 either attended the chemist and druggist department or the sanitary inspectors' class or were hospital assistants undergoing post-collegiate training. As regards dental surgery, 30 lectures were delivered during the session and practical dentistry in the out-patient department of the General Hospital was available. With respect to race, caste, and sex the 327 students were classified as follows: Europeans and Eurasians, 57 males and 22 females; native Christians, 44 males and six females; Brahmans, 110 males; non-Brahmans, 78 males and three females; Mahomedans, five males; and Parsees, two males.

June 26th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Hospital Affairs.

THE annual meeting of the friends and supporters of the Royal Prince Alfred Hospital, Sydney, was presided over by His Excellency the Governor of New South Wales and was largely attended. The report showed that the number of patients admitted during the year 1906 was 4297, and that the total number under treatment was 4545. Of these 2822 were discharged recovered, 801 relieved, and 248 unrelieved; 380 died, and 294 remained in the hospital on Dec. 31st, 1906. The number of beds in the hospital was 318, and the average number of patients resident daily was 295. The number of attendances in the out-patient and casualty departments was 50,315, and the number of individual patients in these departments was 12,579. The total amount received from contributing patients during the year was £2913 as compared with £2359 in 1905. The financial statement for 1906 disclosed a deficiency of £3843, brought about by the increased number of beds available, and in carrying out works recommended in the secretary's report. The surgical operations performed again showed a large increase, the total number for the year being 2749, against the previous highest number recorded of 2337. It had been necessary to add to the general surgical and medical staffs owing to the increase of work from the opening of the new pavilion. The honorary staff now numbered 29 members. As an outcome of the establishment of the medical gymnastic department the massage work of the hospital had been extended, and there were 15 honorary masseurs and masseuses. The board of directors had proposed that the Government, instead of re-building the Coast Hospital at a cost of £40,000, should send the patients to the Royal Prince Alfred Hospital at an annual payment of £50 a bed, the present cost at the Coast Hospital being £65 a bed. The Premier, in this purpose it would be necessary not only to carry on a campaign against the rats by poison and by Danysz's virus but to disinfect every house, block by block, in the town in such a manner that the rats, fleas, and plague bacilli in the houses and rat runs were destroyed. It is possible to disinfect by Clayton's machines every house in Poona in the course of six months at an approximate cost of £1 a house, exclusive of the plant. I have not been able to ascertain exactly the number of houses in Poona but there are certainly not more than 20,000. After the disinfection the plant, with the exception of two machines, could be used for other towns or districts. The two machines left would be sufficient, with the other precautions, to prevent the disease when imported from spreading and assuming epidemic proportions.

CONCLUSION.

It will be noted that my whole thesis in this lecture is based on the necessity of the formation of a special and trained plague service for the prevention and mitigation of plague in India. If this service is organised on proper lines and on a liberal basis the rest will follow. But steps must be taken for it to be done quickly if more stupendous disasters than those of the present year are not to follow and if the great danger to the people of India is to be averted.

Three Clinical Lectures

ON

GENERAL SURGICAL ANÆSTHESIA.

Delivered at the London Hospital,

BY FREDERIC W. HEWITT, M.V.O., M.A., M.D. CANTAB.,

EMERITUS LECTURER ON ANÆSTHETICS.

LECTURE II.[1]

Delivered on June 21st, 1907.

THE TWO DISTINCT VARIETIES OF SURGICAL SHOCK MET WITH DURING GENERAL ANÆSTHESIA.

GENTLEMEN,—I hope to-day to be able to interest you in a subject of considerable importance—the incidence of surgical shock during general anæsthesia. The subject is important not only intrinsically but also because by its careful and clinical consideration we shall, I think, be able to explain some of those mysterious deaths which occur immediately an operation is begun during light anæsthesia and because, as I shall hope to prove to you, the anæsthetist has it in his power, by carefully selecting the anæsthetic and adjusting the degree of anæsthesia, to prevent and successfully treat most cases of surgical shock. I need hardly remind you that the operations and procedures of surgery are capable of producing very definite effects of their own upon unconscious patients. Some of these effects are so obviously dependent upon the operation that no mistake as to their origin is possible; others, however, may so closely simulate those arising from other causes, such as the action of the anæsthetic itself, that mistakes as to their true nature may readily be committed. Time will not permit me to-day to deal with all the phenomena which may arise as the direct or indirect result of surgical procedures during general anæsthesia. I must, therefore, omit all reference to the interesting but difficult question as to the nature of the phenomena which may occur when operations are ineptly commenced so early in anæsthetisation that pain is actually experienced, although it may possibly be subsequently forgotten. I propose, in fact, to deal only with the thoroughly unconscious though not necessarily deeply anæsthetised patient. I must also exclude from consideration the effects of profuse or continuous hæmorrhage during general anæsthesia, although you will readily understand that the phenomena which I am about to discuss to-day are frequently associated with phenomena referable to hæmorrhage. Similarly modifications in general anæsthesia resulting from the adoption of certain postures, from prolonged cutaneous exposure, or from the entry of air into veins will not admit of discussion on this occasion. I propose, in short, only to bring before your notice to-day certain more or less sudden states which may arise during artificially induced unconsciousness—states which are referable to violent nerve stimulation or nerve injury in the course of some surgical operation and to which the term "surgical shock" may therefore appropriately be applied.

Soon after the introduction of anæsthetics into practice it became obvious that surgical operations, and particularly certain surgical operations, were capable of producing in anæsthetised patients certain special effects of their own quite apart from those referable to hæmorrhage. Thus as far back as 1853 Bickersteth of Liverpool recorded cases in which sudden but usually temporary pulse disappearance had occurred at the very moment that some particular surgical procedure was taking place, and he believed that certain of the chloroform fatalities which had then been chronicled were to be ascribed to the shock of the operation. In subsequent years other observers also recorded instances in which during such procedures as the division of the optic nerve, the removal of the testicle, or tooth extraction sudden syncope arose. Now, although I do not deny that surgical shock such as we are considering may, under certain conditions, prove fatal, I wish to impress upon you the important fact that by thoroughly understanding the circumstances in which this surgical shock may arise the anæsthetist may usually, if not invariably, prevent it assuming dangerous or fatal proportions. At the present moment the subject is surrounded by an atmosphere of doubt and dogma and if we can in any way clear that atmosphere an important step will have been taken.

There are at the present time two prevalent misconceptions concerning surgical shock. One of these is that this condition when it arises during general anæsthesia is necessarily a primarily circulatory state, whereas, as I shall presently explain to you, it may start by reflex respiratory embarrassment or arrest and only acquire circulatory importance after the respiratory embarrassment or arrest has existed for some little time. There are, indeed, two distinct varieties of surgical shock—the *respiratory*, in which respiration is primarily and reflexly affected, and the *circulatory*, in which circulation is primarily and reflexly affected. If, as may happen, respiratory shock becomes associated with a failing circulation, or if circulatory shock becomes associated with a failing respiration, a state of *mixed or composite shock* becomes established. The second misconception is that circulatory surgical shock is essentially a phenomenon of light anæsthesia, whereas it is exactly the reverse, for it is met with, as a general rule, after the corneal reflex has been abolished, and therefore at a stage in anæsthetisation when it may easily be, and frequently is, mistaken for simple over-dosage. It is curious that this second misconception should have prevailed for so long. The most likely explanation of the persistence of this erroneous belief is that in a large number of the cases in which it has been supposed that primarily circulatory shock has arisen during light anæsthesia a mistake in diagnosis has been made and that a primarily *respiratory* condition has in reality been present. Respiratory shock is, in fact, the shock of light anæsthesia and circulatory shock that of deep anæsthesia. For upwards of half a century this second misconception has been permitted to influence the profession, with the result that a large number of lives have been sacrificed. You will readily understand that when once the error has been committed of mistaking sudden and primary respiratory arrest for sudden and primary circulatory arrest the consequent error will almost certainly be committed of applying restorative measures to the circulation instead of to the respiration, with the result that in certain cases valuable time will be lost and a fatal result follow.

Minor degrees of reflex respiratory and of reflex circulatory disturbance, as the result of some surgical procedure, are very common in practice and usually attract little or no attention. When, however, the conditions are favourable the respiratory embarrassment or the circulatory depression, as the case may be, may be very noticeable, and it is with these definite or acute conditions that we are here particularly concerned.

RESPIRATORY SHOCK.

The subjects most likely to display respiratory shock are those whose air passages are, from some natural or pathological cause, specially liable to become obstructed. Young and vigorous subjects, those of obese habit, and those

---

[1] Lecture I. was published in THE LANCET of July 20th, 1907, p. 139.

Graz: Dr. Hans Eppinger has been recognised as *privat-docent* of Internal Medicine.—*Strasburg*: Dr. Baer has been recognised as *privat-docent* of Internal Medicine.—*Vienna*: Dr. Karl Funke has been appointed Professor of Surgery in succession to Dr. von Mosetig-Moorhof.—*Zürich*: Dr. Monnier has been recognised as *privat-docent* of Surgery.

Cirrhosis of the Liver in a Child.—An inquest was held at the Swansea workhouse on July 12th relative to the death of a male child, aged two years. After hearing the medical evidence the jury returned a verdict that "Death was due to cirrhosis of the liver, caused by alcohol." The coroner severely censured the mother.

Caledonian Medical Society.—The annual meeting of this society will be held at the Royal Eye Hospital, Bradford, on Thursday, July 25th, under the presidency of Dr. Andrew Little of Bradford. The annual dinner will take place on the same evening in the Midland Hotel, Bradford.

Death Caused by Silicated Cotton.—An inquest was recently held at Plymouth relative to the death of a shipwright who had been working with silicated cotton on board H.M.S. *Minotaur*. The superintendent of Devonport dockyard has now ordered that men using that substance shall wear respirators. These respirators will be made of old bunting, which has been found by experience to be a suitable material.

Donations and Bequests.—Under the will of the late Dr. Robert Barnes St. George's Hospital will receive £500 and the medical school attached to that institution a like sum. The Epsom College and the "Dreadnought" Seamen's Hospital and St. Thomas's Hospital also receive £500 each. The Royal Maternity Charity will receive £300 and the London Hospital Medical School and the Princess Alice Memorial Hospital, Eastbourne, £200 each.—Lord Kilmorey, chairman of Charing Cross Hospital, has received a second donation of £1000 from Lady Wantage towards the liquidation of the balance due on the building debt.

West Ham and East London Hospital.—The foundation-stone of the new building in extension of the present structure is to be laid at 2.30 P.M. on Saturday, July 27th, by the Duchess of Marlborough. The Bishop of St. Albans and the Bishop of Barking, together with the honorary chaplain of the hospital, who has kindly consented that the choir of St. John's Church, Stratford, shall sing a dedicatory hymn, will assist in the ceremony. The architect is Mr. H Percy Adams. Immediately after the ceremony an "At Home" will be held in the hospital, where light refreshments will be served and a plan of the extension of the existing hospital explained to the visitors.

School Hygiene in Switzerland.—The Swiss Society for the Study of School Hygiene met recently at St. Gall when the principal subject of debate was the hygiene of the teaching staff. Dr. Sandoz, who opened the discussion with a paper, demanded a medical examination of candidates both on entering and on leaving the training college. He also asked for a survey of the conditions of service in Swiss schools. This survey should be divided into two parts. The medical report should give statistics of mortality and sickness in the several cantons, in the different groups of schools, and among the different classes of teachers. The second part of the inquiry should relate to the social conditions of the teaching profession, the condition of their dwellings, the graduation and amount of their salaries, and the conditions governing insurance and pensions. When these statistics had been collected an attempt should be made through the directors of education to make the conditions of service more uniform in the cantons and to insure that the more salient features of local hygiene should be respected. As regards personal hygiene, Dr. Sandoz advocated the issue of a teachers' vade mecum of information on points particularly important for the profession. In this he was supported by Dr. Zollinger of Zürich, who thought that the training colleges took pupils too early. He wished to see the minimum age of admission raised to 18 years and the hours of professional study reduced to 15–20 per week so that sufficient time might remain for private study and exercise. 15 other speakers took part in the discussion, at the close of which motions were carried to the following effect:—That the attention of educational authorities should be drawn to the care of the teacher's health as being of as much importance as that of the pupil; that all candidates for admission to a training college should be required to pass a medical examination which should be repeated on leaving; that school and personal hygiene should be included in the syllabus of the training college and that the instruction should be given by a qualified medical man. A committee was appointed to approach the Home Office with the view of carrying out a census of teachers and conditions of service and of arranging for the issue of a pocket-book of hygiene for teachers.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced:—Dr. Max Schüller of Berlin, whose writings on surgery are known far beyond his own country. He was a pupil of Thiersch and Czermak in Leipsic.—Dr. Emanuel Mendel, medical privy councillor of Berlin.—Dr. Josef Schrank, chief surgeon of police in Vienna and author of various papers on public hygiene.—Dr. Heinrich Jordan, professor of gynæcology in the University of Cracow.—Dr. F. M. Costa of Ajaccio, corresponding member of the Paris Academy of Medicine.

Mental Aberration of Engine-drivers.—In the *Engineer* of July 12th it is stated that the driver of a freight train standing in the Gare du Nord Station, Brussels, went mad and started the engine at full speed on the line to *Antwerp*. Regardless of signals the train had passed several stations and had reached Mechlin when the fireman succeeded in overpowering the driver and shutting off steam. We knew of a case many years ago in which an engine-driver on a Welsh railway deliberately drove an engine through the closed doors of an engine-shed. He was not able to explain why he did so and was removed to the county asylum at Abergavenny where he showed no tendency to violence or excitement but ataxia of the legs soon made its appearance.

Royal Society of Medicine: The Visit of the Therapeutical Section to Oxford.—The Therapeutical Section of this society met on July 6th at the University of Oxford, the visit having been arranged for the Therapeutical Society before it dissolved. The members were received at the entrance to Queen's College by Sir Thiselton-Dyer, the first President of the old society. After a glance at the buildings and some of the other colleges he conducted the party to the museum, where Professor W. Osler was waiting ready to point out the beauties of the library and to show the way to the laboratories. The first visited was that of Professor F. Gotch, who explained some of his most recent investigations on the action of the heart. He pointed out that his predecessor, Professor Burdon-Sanderson, had conducted his experiments on the empty heart, which revealed that the ventricular contraction began at the base and terminated at the apex. However, Professor Gotch had, by delicate electrical experiments on the active heart *in situ*, shown that the contraction commenced at the base, travelled to the apex, and terminated at the aortic base; this was graphically displayed and many interesting diagrams and photographs were shown. He next demonstrated a means of at once determining the point of near vision of anyone, the method depending on the different focal lengths of the red and violet rays. Dr. W. Ramsden in the same laboratory had arranged a number of beautiful experiments, which he described, determining the separation of solids in the surface layers of solutions and suspensions. Proceeding to the anatomical rooms Professor Arthur Thomson showed a thorax with complete transposition of the viscera and a dissection of a calf's heart displaying to perfection the auriculo-ventricular bundle (His), and demonstrating how important a structure it was; also some enlarged photographs (*stereoscopic*) of the very early human embryo. In the pathological rooms there was an exhibition of macroscopic and microscopic specimens and Dr. A. G. Gibson gave a demonstration of Jacquet's polygraph (modified) on a lad. Lunch followed in Queen's College and in the afternoon many places of interest, including the Botanical Gardens, were visited. Professor Osler gave a garden party at his home to which all were invited. He had laid out for inspection his rare and interesting books and everyone thoroughly enjoyed the privilege of examining them. The section dined in the evening at Queen's College. Sir James Sawyer proposed the health of the President, Dr. T. E. Burton Brown, C.I.E., and referred to the good work done by the society of which he was the "father" and the fitness of his being the first prevent circulatory shock. The operations in which I have most frequently met with this complication of general anæsthesia have been those within the abdomen, those upon the kidney, and those upon the breast. It must be remembered, however, that these operations are amongst the commonest in major surgery. Of my 71 cases of circulatory shock, 26 occurred during intra-abdominal operations, 12 during breast operations, ten during renal operations, six during rectal operations, five during gynæcological operations, five during deeply seated operations upon the neck, three during vesical operations, one during a tongue operation, one during the passage of a lithotrite, one during a skin incision, and one during an operation for castration. Traction upon the intestine, stomach, or omentum, partial or complete evisceration, dragging upon the uterus, ovary, or gall-bladder, and similar procedures are specially likely to produce circulatory shock during deep chloroform anæsthesia. I have known sudden and apparently alarming syncope to be caused by the operator passing his finger behind the pectoral muscles and pulling them forwards prior to their division in the course of an ordinary breast operation. Operations in the neighbourhood of the vagus are also liable to be attended by sudden circulatory shock. For obvious reasons operations upon the brain and spinal cord frequently cause severe shock and call for special care on the part of the anæsthetist. During the operation of prostatectomy whilst the prostate is being removed there is also a tendency for the pulse to vanish completely and in severe cases for respiration to cease as the result of the temporary suspension of cerebral circulation. Rectal, gynæcological, and other operations within and upon the genito-urinary organs are also liable to cause circulatory shock in patients deeply under chloroform or a mixture rich in chloroform. My experience in anæsthetising for ophthalmic operations has been very limited, but I may remind you that cases of sudden fatal syncope during the division of the optic nerve have in past years been recorded. As to operations within and about the mouth, the nose, and the throat, these have been, in my experience, remarkably free from circulatory shock, probably because in such cases one generally maintains a moderate as opposed to a deep anæsthesia. With two possible exceptions, indeed, I have never met with this complication in nose or throat cases, although I have administered chloroform (after ether) in the sitting posture in many hundreds of such cases. Tooth extraction during nitrous oxide anæsthesia is practically never attended by circulatory shock for reasons which you will understand after what I have already said. It is probable that in most of the reported cases the state was one originally respiratory in character. Similarly, extensive skin incisions more often primarily disturb respiration than circulation. I have never seen circulatory shock during an operation for mastoid disease.

The clinical phenomena of circulatory surgical shock may vary from a barely noticeable effect upon the pulse to the most alarming and apparently fatal syncope. In mild cases there may be nothing beyond a slowing, feebleness, or irregularity of pulse, possibly coupled with slight pallor, the respiration remaining unchanged and perfectly satisfactory. In more marked cases these symptoms are associated with some coldness and perspiration of the nose, forehead, and other parts, a loss of normal moisture inside the lips, a slight separation of the eyelids, and a lessening in the depth of respiration. A change from stertorous to tranquil breathing is a noticeable phenomenon in some cases and is interesting as supporting the view that stertor is usually a spasmodic rather than a paralytic phenomenon. The disappearance of stertor is probably analogous to want of closure of the lids. In the most acute cases pallor and pulse disappearance, wide separation of the hitherto closed lids, marked dilatation of the pupils, and suspension of respiration are the prominent manifestations, the symptoms occurring roughly in the order named, but possibly in such rapid succession that the whole seizure appears to be momentary. In the case already referred to, in which acute shock occurred as the result of vigorous traction upon the pectoral muscles, the patient presented all the appearances of sudden death. I have observed a precisely similar appearance of the patient during certain deeply seated operations in the neck, probably from direct interference with the vagus. In several cases I have noticed that the pulse, although very slow, has retained a fair volume during the few beats which have immediately preceded its cessation. In others, a curious batch of deep respirations—five or six in number—has been a prominent feature of the acute seizure, the batch occurring immediately before breathing has ceased. In a few cases I have observed local pulselessness. Thus during an abdominal exploration in a jaundiced patient whose arms were pinned up both radial pulses disappeared, although the temporal artery could be felt beating. The anæsthetic in use at the time was chloroform and the patient was fully, but not too deeply, anæsthetised. Although the depth of anæsthesia was lessened and the C.E. mixture substituted for chloroform, the radial pulses remained absent till the abdomen was being closed when, the arms still being pinned up, the wrist pulses returned. I have met with a somewhat similar case in a child during a mastoid operation, the radial pulse of the opposite side twice becoming imperceptible during the operation. In this case, as in the other, the patient's posture doubtless favoured the pulse disappearance, a slight pressure upon or flexion of certain arteries being quite sufficient, with the general low pressure present, to arrest the pulse.

There are two important clinical points in these cases—viz.: (1) that the shock is essentially one which is primarily circulatory, respiration only ceasing when the pulse has vanished; and (2) that even though the shock be acute and threatening in its manifestations it is almost invariably of a transient character. It will be convenient to say a few words on these two points.

1. The clinical phenomena of the cases now under consideration would seem to indicate that the surgical stimuli to which reference has above been made, acting through sensory or sympathetic nerves, primarily affect, in most cases, both the cardio-inhibitory and the vaso-motor centres, with the result that a fall in blood pressure takes place, the degree of which is in direct proportion to the severity of the stimulus and to the extent to which the blood pressure had been lowered by the anæsthetic when the nerve injury occurred. According to Crile, whose physiological researches on surgical shock are now well known, the condition is principally one of vaso-motor paralysis brought about by the nerve injury paralysing the main vaso-motor centres, the result of the paralysis being a fall of blood pressure and an accumulation of blood within the venous system and particularly within the vessels of the splanchnic area. Crile does not apparently attach much importance to the cardio-inhibitory element in surgical shock, but clinically there would seem to be certain cases in which the cardio-inhibitory effect is more conspicuous than the vaso-motor effect. I have, for example, often met with simple bradycardia or with temporary cardiac arrest without pallor or any other noticeable symptoms during certain operations under ether, during others under moderate chloroform anæsthesia, and during others, again, under chloroform administered to the full surgical degree to patients in the Trendelenburg posture. Crile does not appear, moreover, to have studied the effects of given stimuli in different degrees of chloroform anæsthesia or the effects of such stimuli under different anæsthetics administered to the same degree. There can be no doubt, however, that in human beings these different conditions are of considerable importance, as already indicated.

2. The essentially evanescent character of typical surgical shock during general anæsthesia has been a conspicuous feature in practically every case of which I have notes. Of 71 cases, not one was fatal; and although in some of them I felt considerable anxiety I am gradually coming to the conclusion that there is little or no occasion for alarm. Even in the most marked cases recovery came about within a couple of minutes at the outside, and in many of them within a minute. At the same time I can readily conceive that with a deeper chloroform anæsthesia than that which existed, or with less prompt or wrong treatment, serious results might have occurred.

When respiratory shock becomes quickly followed by circulatory depression, as may be the case in weakly subjects and in those with degenerated cardio-vascular systems, or when circulatory shock is so acute that respiration rapidly ceases as the result of the sudden cerebral anæmia, a state of mixed or composite shock becomes established.

The diagnosis of circulatory shock is an important matter, for upon it depends the proper treatment of the condition. It is distinguished from: (1) respiratory shock by the initial phenomena being circulatory, the pulse changes, pallor, &c., occurring before any respiratory effects are observed. In respiratory shock, moreover, there are, as a rule, muscular spasm, stertor or stridor, and cyanosis; whilst

THURSDAY, JULY 11TH.

The Evils of Alcohol and Public Elementary Schools.

Mr. **WEDGWOOD** asked the *President of the Board of Education* whether his attention had been drawn to a volume by Sir Victor Horsley and Dr. Mary Sturge, entitled "Alcohol and the Human Body," in which it was stated that evidence was steadily accumulating that the stunted frames and weak development of many poor children were at any rate partly due both directly and indirectly to the action of alcohol; that one of the most frequent causes of evil habits and of sexual immorality among young people was the taking of alcohol; that for the sake of national morality as well as physique it was clear that in no form whatever should alcohol be used by the young, either in childhood or adolescence; if he would say what teaching, if any, was given on the subject in the public elementary schools; and whether he would prescribe and enforce lessons thereupon in all schools over which he had any authority.—Mr. **McKENNA** replied: The answer to the first part of the question is in the negative, but I would draw my honourable friend's attention to Paragraph 7 in the prefatory memorandum to the new code of Regulations for Public Elementary Schools and to Paragraph 4 in the prefatory memorandum to the new *Regulations for Training Colleges* just issued which will show, I think, that the Board of Education is doing its best to secure adequate and efficient teaching in the important matters referred to in the honourable Member's question.

The Plague in India.

Dr. **RUTHERFORD** asked the Secretary of State for India whether he had yet received answers from the Government of India to his questions in April in reference to the special medical staff deputed to combat the plague.—Mr. **MORLEY** answered: I have heard from the Government of India that local governments are engaged in collecting the needful information, but as the statistics wanted extend over a series of years they cannot be procured without some delay. The subject of the plague is engaging my particular attention and full papers will shortly be laid on the table.

The Plague in Egypt.

Dr. **RUTHERFORD** asked the Secretary of State for Foreign Affairs whether he could say what was the number of deaths from plague in Egypt during January, February, March, April, May, and June, respectively, this year.—Sir **EDWARD GREY** replied: The figures are—January, 8; February, 46; March, 204; April, 147; May, 184; and June (up to 17th), 111.

Medical Inspection of School Children.

In the course of the discussion on the Education Vote in Committee of Supply several Members urged the President of the Board of Education to make provision for organising a central medical department to assist and guide local authorities in instituting the medical inspection of school children.—Mr. **McKENNA**, in reply, said that if the Bill dealing with this subject passed it was the intention of the Board of Education to establish a medical bureau which would guide and advise the local authorities as to the nature of the work they would have to do under this Act. He hoped that when the names were published the House would be fully satisfied.

MONDAY, JULY 15TH.

Allowances to the Royal Army Medical Corps.

Mr. **CAMPBELL** asked the Secretary of State for War whether he was aware that officers of the Royal Army Medical Corps, under the substantive rank of colonel but holding the appointment of senior medical officer in a command in India, had been refused the additional daily allowance of 5*s.* to which such officers were by the terms of Paragraph 4 of the Army Order of Jan. 10th, 1907, expressly entitled if serving abroad, and that such refusal had been justified on the ground that service in India was not service abroad within the meaning of the Army Order; and, if so, seeing that such a construction was a direct violation of the letter as well as of the spirit of the Order in question he proposed to take any and, if any, what action in the matter.—Mr. **HOBHOUSE** (the Under Secretary for India) answered: The Army Order referred to published a Royal Warrant modifying certain paragraphs of the Pay Warrant of the army, the preamble of which specially exempts the Indian Empire from the sphere within which the warrant is in force. Officers of the Royal Army Medical Corps serving in India receive special Indian rates of pay as laid down in the Indian army regulations and it is not proposed to disturb this arrangement.

The Belfast Health Commission.

Mr. **SLOAN** asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware of the fact that the Belfast Health Commission, consisting of Colonel Harding, an ex-Lord Mayor of Leeds; Dr. Mair, a medical inspector of the Local Government Board of England; Dr. Chalmers of Glasgow; and two inspectors of the Irish Local Government Board, appointed on Feb. 11th, 1907, to inquire into the cause of the high death-rate in Belfast, had held 24 sittings, all the evidence at which had been taken on oath, and whether he would state what statutory authority any person or persons other than inspectors of the Local Government Board had to hold inquiries under Section 209 of the Public Health (Ireland) Act, 1878, or to take evidence on oath.—Mr. **BIRRELL** answered: The number of sittings held so far by the Commission referred to is correctly stated in the question. All the evidence has been taken on oath. There is nothing to prevent other persons from being associated with inspectors of the Local Government Board in holding inquiries under Section 209 of the Public Health (Ireland) Act, 1878. The power of administering an oath is, however, vested only in inspectors and this power has not been exercised by any of the other gentlemen on the Commission.

Epileptics and the Workmen's Compensation Act.

Mr. **GULLAND** asked the Secretary of State for the Home Department whether he was aware that throughout the country there were many workers subject to epileptic fits; that under the Workmen's Compensation Act the insurance companies would not undertake the risk of insuring them against accidents; that, contracting out not being allowed, they were in danger of losing their employment; and what steps, if any, he proposed to take to prevent this class from being deprived of the opportunity of earning a livelihood.—Mr. **GLADSTONE** said in reply: I have no official information on the matters referred to in the question. I believe, however, it is a fact that quite apart from the Workmen's Compensation Act epileptics have difficulty in finding employment. The new Act may aggravate that difficulty, though such cases might have been provided for under an amendment which I moved on the report stage of the Bill and which after being left to the judgment of the House was rejected. The matter is one which obviously cannot be considered with reference merely to the effects of the Act, and as my honourable friend will be aware the whole question of the treatment of the feeble minded, including epileptics, is under the consideration of a Royal Commission the report of which may be expected shortly.

The International Congress on School Hygiene.

Dr. **RUTHERFORD** asked the President of the Board of Education whether His Majesty's Government would invite foreign powers to send delegates to the International Congress on School Hygiene to be held in London next month.

Mr. **ALDEN** further asked the Secretary to the Board of Education whether he would consider the possibility of giving an official reception to the delegates of the International Congress on School Hygiene.

Mr. **RAMSAY MACDONALD** also asked the right honourable gentleman whether the Board was taking any official part in the International Congress on School Hygiene; whether the Board had approached the Foreign Office with a view of securing the official representation of foreign countries at the Congress; whether any communication between the two offices on this subject had taken place; and what steps his department had taken to carry out the promise made by its representative at Nuremberg, as printed in the transactions of the Congress, that the Government would officially recognise the Congress and would feel honoured by its presence in London.—Mr. **McKENNA** (in replying to the three questions together) said: The Board of Education, while considering it inadvisable to comply with the suggestion of the hon. Member for Tottenham, is greatly interested in the approaching Congress on School Hygiene and has intimated its intention of sending three of its officers to attend it. I hope to derive much information from its proceedings and I have done my best to facilitate its deliberations by arranging for special investigations and reports to be prepared in elucidation of some important matters that will come under discussion. The various foreign countries have already received invitations which were forwarded to the respective Governments through the Foreign Office. A considerable number have signified their intention to send representatives. The University of London is finding rooms for the Congress and I am also placing certain rooms at South Kensington at its disposal. I have thus been able to carry out to the fullest extent all that was promised by the Board's representative at the Nuremberg conference.

TUESDAY, JULY 16TH.

The Plague in India.

Dr. **RUTHERFORD** asked the Secretary of State for India what was the number of deaths from plague during June in the Punjab and in the whole of India; and what was the total for the six months in the Punjab and in India.—Mr. **MORLEY** replied: The figures for June are: Punjab, 58,821 deaths; whole of India, 69,064. For six months ending June: Punjab, 632,953; whole of India, 1,060,067.

The Registration of Nurses.

Mr. **HART-DAVIES** asked the Secretary of State for the Home Department whether he would consider the advisability of establishing a Government system of certificates and registration of trained nurses.—Mr. **GLADSTONE** answered: This matter has been under consideration for some time, but serious difficulties stand in the way of the establishment of any such system as is proposed. I am not prepared to take any action in the matter.

WEDNESDAY, JULY 17TH.

The Increase of Trachoma.

Mr. **LEVERTON HARRIS** asked the Secretary of State for the Home Department whether his attention had been drawn to the increase in cases entering hospitals suffering from trachoma, and what steps were being taken to prevent the spread of this contagious disease.—Mr. **GLADSTONE** answered: Trachoma comes within my jurisdiction only so far as the operation of the Aliens Act is concerned. It is a disease on account of which alien passengers who are subject to the provisions of that Act may be excluded from this country, and since that Act came into force numerous cases have been excluded.

BOOKS, ETC., RECEIVED.

BEMROSE AND SONS, LIMITED, 4, *Snow Hill*, London, E.C., and Derby.

The Book of the League of Mercy. Published under the Patronage of Their Royal Highnesses the Prince and Princess of Wales, Grand President and Lady Grand President of the League of Mercy, Their Royal Highnesses Prince and Princess Christian of Schleswig-Holstein, Her Royal Highness Princess Alexander of Teck, Lady President of the Epsom-Esher (with Godstone-Caterham) and Kingston-Surbiton (with Wandsworth-Putney) Districts, His Serene Highness Prince Alexander George of Teck, K.C.V.O., D.S.O., President of the Kingston-Surbiton (with Wandsworth-Putney) District, Her Highness Princess Victoria of Schleswig-Holstein, Lady President of the Berks, Bucks, Oxon, and Hants *Districts*, and *Her Highness* Princess Louise Augusta of Schleswig-Holstein. Edited by Rev. P. H. Ditchfield, M.A., F.S.A. Price 5*s.* net.

may with advantage be tilted slightly by placing blocks under the lower end of the table. Should the circulatory shock be associated with shallow breathing the withdrawal of the anæsthetic may be coupled with chest pressure during expiration. In acute cases in which respiratory arrest quickly follows pulselessness the operation must be temporarily suspended, the patient's body drawn towards the anæsthetist, so that the head hangs over the end of the table, and rhythmic chest compression commenced. By alternately forcibly compressing the sides of the chest with the flat hands and relaxing the pressure air may generally be made to pass out of and into the lungs, but if there be the slightest difficulty in securing this end systematic artificial respiration must be practised. As already mentioned, recovery almost invariably takes place within a minute or two. If it be delayed the artificial respiration must be combined with more or less complete inversion of the body. Although the state we are considering is essentially a circulatory one care must be taken to avoid the slightest obstruction in respiration. Personally, I am not a believer in the use of drugs in this condition: lung ventilation and proper posture are the two cardinal remedies. In one of the most acute cases of surgical shock that I ever witnessed the pulse at both wrists disappeared for 20 minutes, but no remedial measures beyond keeping the legs high and the head low and maintaining free respiration were adopted: at the conclusion of the operation (the first stage of Kraske's operation) the pulse and colour had returned and the patient's condition became quite satisfactory. The patient made such a good recovery, indeed, that the second half of the operation was performed in two or three days' time. In exceptionally bad cases in which the patient's condition does not rapidly improve it may perhaps be advisable to administer a saline injection or infusion.

CONCLUSIONS.

1. Two distinct varieties of surgical shock are met with during general anæsthesia: (1) respiratory and (2) circulatory. In pure respiratory shock the respiration is primarily affected (reflexly), the circulation only failing secondarily. In pure circulatory shock the circulation is primarily affected (reflexly), the respiration only failing secondarily.

2. When respiratory shock becomes complicated by circulatory, or circulatory by respiratory, a state of mixed or composite surgical shock is produced.

3 Respiratory surgical shock, which may occur under all anæsthetics, is most common during *light* or *moderate* anæsthesia—i.e., before the corneal reflex has vanished; whilst circulatory shock, which is far more common under chloroform than under other agents, is met with during *profound* narcosis.

4. The risk of preparing patients or commencing operations before full anæsthesia has been secured is from the *respiratory* and not from the *circulatory* side, as is generally believed.

5. Respiratory shock may arise during any operation, but it seems specially liable to complicate operations upon the rectum, urethra, abdominal organs, uterus, perineum, and kidney. The immediate cause of the respiratory arrest is usually a reflex spasm affecting either (*a*) the tongue, fauces, palate, and adjacent parts, and having stertor as its audible expression; (*b*) the larynx, and producing stridor; or (*c*) the respiratory muscles, and bringing about respiratory spasm.

6 Circulatory shock is chiefly, if not exclusively met with during operations upon parts which possess important nerves or are rich in nerve supply. The immediate cause of the circulatory phenomena is usually a more or less sudden relaxation or paralysis of the vaso-motor system, generally associated with some cardiac inhibition. In some cases the effect produced by the nerve injury is chiefly one of cardiac inhibition

7. The most favourable conditions for the occurrence of acute and threatening respiratory shock are: (1) partially established anæsthesia; (2) manipulations or operations upon sensitive parts; and (3) the presence of an airway liable to become occluded.

8. The most favourable conditions for the occurrence of acute and threatening circulatory shock are (1) deep chloroform anæsthesia; (2) the horizontal, semi-recumbent, or sitting posture; and (3) intestinal, omental, uterine, or renal traction.

9. Certain subjects, by reason of the conformation of their upper air passages, seem specially liable to respiratory shock, whilst others, possibly from some abnormal instability of their vaso-motor systems, may perhaps be prone to circulatory shock. The state of the heart itself seems to have little or no influence.

10. There may be such a close resemblance between simple chloroform overdosage and circulatory shock under chloroform that the latter condition may be readily mistaken for the former.

11. Whilst surgical shock may undoubtedly be largely prevented by gentleness on the part of the surgeon, its prevention is also largely in the hands of the anæsthetist. The respiratory variety may usually be avoided by securing full anæsthesia before the patient is moved or the operation is begun, and by so adjusting the degree of anæsthesia that reflex modifications in respiration are as far as possible eliminated. As circulatory shock is very rare under ether it may generally be prevented by employing this anæsthetic. Should chloroform or a chloroform mixture be used there are only two ways in which to prevent circulatory shock during certain operations—viz., (1) to avoid too deep an anæsthesia, or if the patient be deeply anæsthetised to lessen the depth of anæsthesia so that the corneal reflex returns; or (2) to place the patient in the Trendelenburg posture. With the rarest exceptions, circulatory shock is never seen in the Trendelenburg posture.

12. The treatment of respiratory shock is to re-establish respiration as quickly as possible by such procedures as separating the clenched teeth, sponging out the fauces, pushing the lower jaw forwards, tongue traction, artificial respiration, and if need be, laryngotomy and direct lung inflation.

13. The treatment of circulatory shock in its milder form is simply to lessen the depth of anæsthesia and to substitute the C.E. mixture or ether for chloroform. In its acute form circulatory shock must be treated by withholding the anæsthetic, lowering the head, raising the feet, and, should respiration show signs of failure or actually cease, by performing artificial respiration. Unless the patient be so deeply anæsthetised by chloroform as to be in peril from this additional quarter recovery from circulatory shock may generally be effected very rapidly—within a minute or two—and the operation may then be proceeded with. Drugs are of little or no value as compared to the lines of treatment here indicated.

THE CARRIAGE OF INFECTION BY FLIES.[1]

BY R. M. BUCHANAN, M.B. GLASG., F.F.P.S. GLASG.,
BACTERIOLOGIST TO THE CORPORATION OF GLASGOW.

I PURPOSE to present a few experiments in demonstration of the part which flies are capable of playing as agents in carrying and spreading infection. The experiments were undertaken as opportunity offered to test the value to be attached to the opinion frequently expressed of late years and emphasised by observations in the Cuban and South African campaigns that flies convey on their bodies infective material and contribute to the spread of certain diseases.

The flies used in the experiments were the common house-fly (*Musca domestica*) and the bluebottle (*Musca vomitoria*). The latter is referred to hereafter in this paper as the blue fly. The flies were allowed a limited contact with infective material and then transferred directly to the surface of a solidified nutrient medium in a Petri capsule, and in some instances to a succession of such surfaces. By rotating the capsule, held at an angle, it was frequently possible to make the insect traverse the greater part of the surface of the nutrient medium, and when its transference to another capsule was desired this was accomplished without injury by means of a pair of curved sterilised forceps.

It may be remarked that the form and structure of the fly's foot (tarsus) are such as render it capable of carrying a large amount of infective material. It consists of five segments or "joints" which are clothed with short hairs and armed with numerous bristles and spines. The terminal segment is also provided at its tip with a pair of moveable claws and a pair of membranous flaps (pulvilli)—the latter coming into action on smooth surfaces (Fig. 1).

The diseases which were made the subject of the experiments were typhoid fever, swine fever, staphylococcal abscess, pulmonary tuberculosis, and anthrax.

---

THURSDAY, JULY 11TH.

The Evils of Alcohol and Public Elementary Schools.

Mr. WEDGWOOD asked the President of the Board of Education whether his attention had been drawn to a volume by Sir Victor Horsley and Dr. Mary Sturge, entitled "Alcohol and the Human Body," in which it was stated that evidence was steadily accumulating that the stunted frames and weak development of many poor children were at any rate partly due both directly and indirectly to the action of alcohol; that one of the most frequent causes of evil habits and of sexual immorality among young people was the taking of alcohol; that for the sake of national morality as well as physique it was clear that in no form whatever should alcohol be used by the young, either in childhood or adolescence; if he would say what teaching, if any, was given on the subject in the public elementary schools; and whether he would prescribe and enforce lessons thereupon in all schools over which he had any authority.—Mr. MCKENNA replied: The answer to the first part of the question is in the negative, but I would draw my honourable friend's attention to Paragraph 7 in the prefatory memorandum to the new code of Regulations for Public Elementary Schools and to Paragraph 4 in the prefatory memorandum to the new Regulations for Training Colleges just issued which will show, I think, that the Board of Education is doing its best to secure adequate and efficient teaching in the important matters referred to in the honourable Member's question.

The Plague in India.

Dr. RUTHERFORD asked the Secretary of State for India whether he had yet received answers from the Government of India to his questions in April in reference to the special medical staff deputed to combat the plague.—Mr. MORLEY answered: I have heard from the Government of India that local governments are engaged in collecting the needful information, but as the statistics wanted extend over a series of years they cannot be procured without some delay. The subject of the plague is engaging my particular attention and full papers will shortly be laid on the table.

The Plague in Egypt.

Dr. RUTHERFORD asked the Secretary of State for Foreign Affairs whether he could say what was the number of deaths from plague in Egypt during January, February, March, April, May, and June, respectively, this year.—Sir EDWARD GREY replied: The figures are—January, 8; February, 46; March, 204; April, 147; May, 164; and June (up to 17th), 111.

Medical Inspection of School Children.

In the course of the discussion on the Education Vote in Committee of Supply several Members urged the President of the Board of Education to make provision for organising a central medical department to assist and guide local authorities in instituting the medical inspection of school children.—Mr. MCKENNA, in reply, said that if the Bill dealing with this subject passed it was the intention of the Board of Education to establish a medical bureau which would guide and advise the local authorities as to the nature of the work they would have to do under this Act. He hoped that when the names were published the House would be fully satisfied.

MONDAY, JULY 15TH.

Allowances to the Royal Army Medical Corps.

Mr. CAMPBELL asked the Secretary of State for War whether he was aware that officers of the Royal Army Medical Corps, under the substantive rank of colonel but holding the appointment of senior medical officer in a command in India, had been refused the additional daily allowance of 5s. to which such officers were by the terms of Paragraph 4 of the Army Order of Jan. 10th, 1907, expressly entitled if serving abroad, and that such refusal had been justified on the ground that service in India was not service abroad within the meaning of the Army Order; and, if so, seeing that such a construction was a direct violation of the letter as well as of the spirit of the Order in question he proposed to take any and, if any, what action in the matter.—Mr. HOBHOUSE (the Under Secretary for India) answered: The Army Order referred to published a Royal Warrant modifying certain paragraphs of the Pay Warrant of the army, the preamble of which specially exempts the Indian Empire from the sphere within which the warrant is in force. Officers of the Royal Army Medical Corps serving in India receive special Indian rates of pay as laid down in the Indian army regulations and it is not proposed to disturb this arrangement.

The Belfast Health Commission.

Mr. SLOAN asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware of the fact that the Belfast Health Commission, consisting of Colonel Harding, an ex-Lord Mayor of Leeds; Dr. Mair, a medical inspector of the Local Government Board of England; Dr. Chalmers of Glasgow; and two inspectors of the Irish Local Government Board, appointed on Feb. 11th, 1907, to inquire into the cause of the high death-rate in Belfast, had held 24 sittings, all the evidence at which had been taken on oath, and whether he would state what statutory authority any person or persons other than inspectors of the Local Government Board had to hold inquiries under Section 209 of the Public Health (Ireland) Act, 1878, or to take evidence on oath.—Mr. BIRRELL answered: The number of sittings held so far by the Commission referred to is correctly stated in the question. All the evidence has been taken on oath. There is nothing to prevent other persons from being associated with inspectors of the Local Government Board in holding inquiries under Section 209 of the Public Health (Ireland) Act, 1878. The power of administering an oath is, however, vested only in inspectors and this power has not been exercised by any of the other gentlemen on the Commission.

Epileptics and the Workmen's Compensation Act.

Mr. GULLAND asked the Secretary of State for the Home Department whether he was aware that throughout the country there were many workers subject to epileptic fits; that under the Workmen's Compensation Act the insurance companies would not undertake the risk of insuring them against accidents; that, contracting out not being allowed, they were in danger of losing their employment; and what steps, if any, he proposed to take to prevent this class from being deprived of the opportunity of earning a livelihood.—Mr. GLADSTONE said in reply: I have no official information on the matters referred to in the question. I believe, however, it is a fact that quite apart from the Workmen's Compensation Act epileptics have difficulty in finding employment. The new Act may aggravate that difficulty, though such cases might have been provided for under an amendment which I moved on the report stage of the Bill and which after being left to the judgment of the House was rejected. The matter is one which obviously cannot be considered with reference merely to the effects of the Act, and as my honourable friend will be aware the whole question of the treatment of the feeble minded, including epileptics, is under the consideration of a Royal Commission the report of which may be expected shortly.

The International Congress on School Hygiene.

Dr. RUTHERFORD asked the President of the Board of Education whether His Majesty's Government would invite foreign powers to send delegates to the International Congress on School Hygiene to be held in London next month.

Mr. ALDEN further asked the Secretary to the Board of Education whether he would consider the possibility of giving an official reception to the delegates of the International Congress on School Hygiene.

Mr. RAMSAY MACDONALD also asked the right honourable gentleman whether the Board was taking any official part in the International Congress on School Hygiene; whether the Board had approached the Foreign Office with a view of securing the official representation of foreign countries at the Congress; whether any communication between the two offices on this subject had taken place; and what steps his department had taken to carry out the promise made by its representative at Nuremberg, as printed in the transactions of the Congress, that the Government would officially recognise the Congress and would feel honoured by its presence in London.—Mr. MCKENNA (in replying to the three questions together) said: The Board of Education, while considering it inadvisable to comply with the suggestion of the hon. Member for Tottenham, is greatly interested in the approaching Congress on School Hygiene and has intimated its intention of sending three of its officers to attend it. I hope to derive much information from its proceedings and I have done my best to facilitate its deliberations by arranging for special investigations and reports to be prepared in elucidation of some important matters that will come under discussion. The various foreign countries have already received invitations which were forwarded to the respective Governments through the Foreign Office. A considerable number have signified their intention to send representatives. The University of London is finding rooms for the Congress and I am also placing certain rooms at South Kensington at its disposal. I have thus been able to carry out to the fullest extent all that was promised by the Board's representative at the Nuremberg conference.

TUESDAY, JULY 16TH.

The Plague in India.

Dr. RUTHERFORD asked the Secretary of State for India what was the number of deaths from plague during June in the Punjab and in the whole of India; and what was the total for the six months in the Punjab and in India.—Mr. MORLEY replied: The figures for June are: Punjab, 58,821 deaths; whole of India, 69,064. For six months ending June: Punjab, 632,953; whole of India, 1,060,067.

The Registration of Nurses.

Mr. HART-DAVIES asked the Secretary of State for the Home Department whether he would consider the advisability of establishing a Government system of certificates and registration of trained nurses.—Mr. GLADSTONE answered: This matter has been under consideration for some time, but serious difficulties stand in the way of the establishment of any such system as is proposed. I am not prepared to take any action in the matter.

WEDNESDAY, JULY 17TH.

The Increase of Trachoma.

Mr. LEVERTON HARRIS asked the Secretary of State for the Home Department whether his attention had been drawn to the increase in cases entering hospitals suffering from trachoma, and what steps were being taken to prevent the spread of this contagious disease.—Mr. GLADSTONE answered: Trachoma comes within my jurisdiction only so far as the operation of the Aliens Act is concerned. It is a disease on account of which alien passengers who are subject to the provisions of that Act may be excluded from this country, and since that Act came into force numerous cases have been excluded.

BOOKS, ETC., RECEIVED.

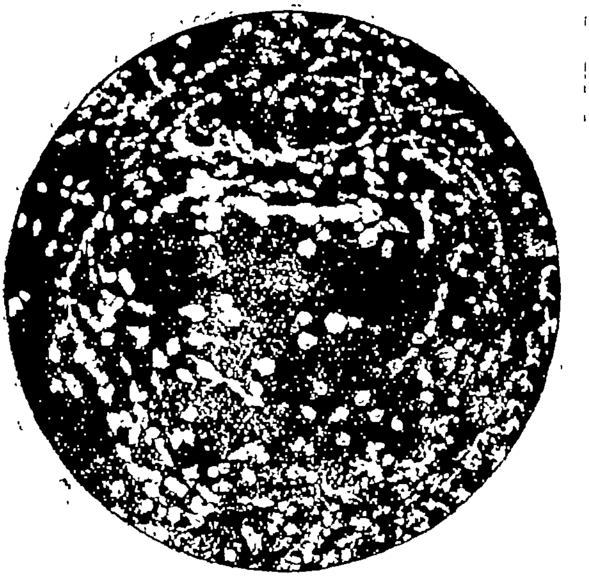
agar in a Petri capsule and was allowed to walk thereon for a short time. A second agar surface was provided on which it was also allowed to walk for the same time. Incubation for 24 hours at 37° C. brought forth on both agar surfaces a very profuse growth of bacillus anthracis (Figs. 2 and 3).[4] It was not anticipated that the second surface would show so much growth, and it would have been of interest and importance had the cultures been extended in a longer series to determine how many fresh surfaces such a fly was capable of infecting. Its potentialities in the direction were altogether underestimated.

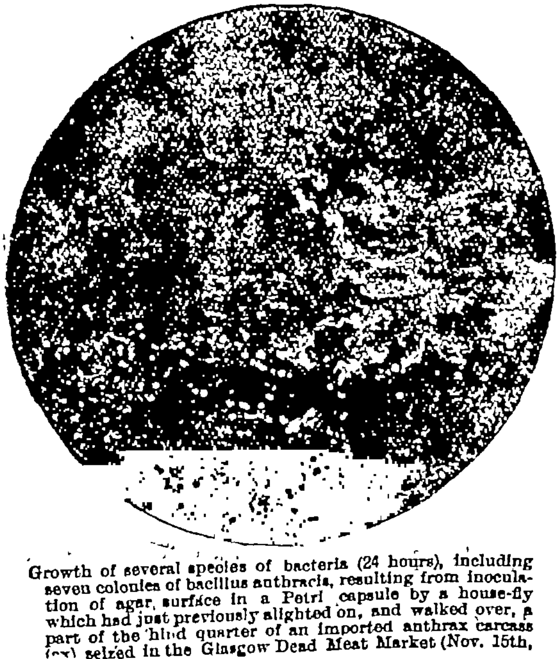
FIG. 3.



The second agar surface traversed by the same blue fly, showing by the profuse growth of bacillus anthracis (24 hours) the large amount of infection which still remained on the insect's feet after contact with the first agar surface.

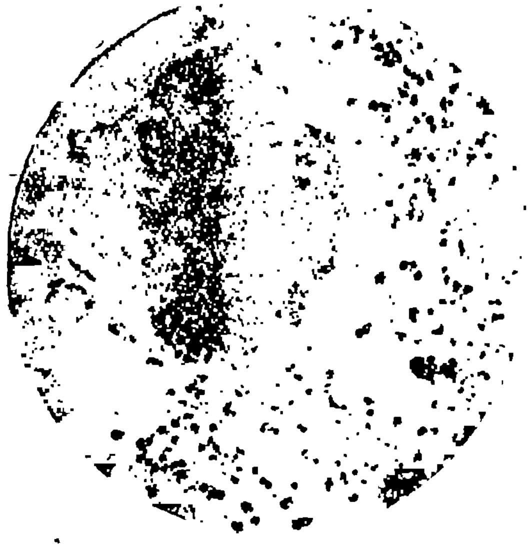
Experiment VIII.—With the view of testing the value of these results under conditions of ordinary experience an anthrax carcass (ox) which had been seized by the veterinary surgeon in the Glasgow Dead Meat Market (November, 1905) was made the subject of experiment. A house-fly was placed under a bell-jar resting on one of the hind quarters of the carcass, the surface of the part being quite firm and dry. When the fly had alighted on and walked over the part several times it was transferred to a Petri capsule and caused to traverse the surface of the nutrient medium. After 24 hours' incubation at 37° C. a growth of various species appeared, including seven colonies of bacillus anthracis (Fig. 4). A second fly, held by the wing by means of forceps, was directed across the cut surface of the kidney and gave rise to a profuse growth of bacillus anthracis, amongst other species, on solidified agar (Fig. 5). A third fly, directed in like manner over the cut surface of the thigh muscles, produced a profuse growth of several species, amongst which were found two colonies of bacillus anthracis.

FIG. 4.



Growth of several species of bacteria (24 hours), including seven colonies of bacillus anthracis, resulting from inoculation of agar surface in a Petri capsule by a house-fly which had just previously alighted on, and walked over, a part of the hind quarter of an imported anthrax carcass (ox) seized in the Glasgow Dead Meat Market (Nov. 15th, 1905).

FIG. 5.



Profuse growth of bacillus anthracis amongst other species (24 hours) resulting from inoculation of agar surface in a Petri capsule by a house-fly which had just previously been allowed to walk over the cut surface of the kidney in the same carcass.

The experiments conclusively show that flies alighting on any substance containing pathogenic organisms are capable of carrying away these organisms in large numbers on their feet and of depositing them in gradually diminishing number on surface after surface with which they come in contact. They further serve to demonstrate the necessity for the exercise of stringent measures to prevent the access of flies to all sources of infection and to protect food of all kinds against flies alighting on it.

Glasgow.

THE ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—Arrangements for the amalgamation of the Royal National and City Orthopædic Hospitals have now been completed and the patients of both hospitals are being seen in the temporary premises of the amalgamated institution, Nos. 45–47, Bolsover-street, immediately behind the old hospital in Great Portland-street. Dr. J. Hughlings Jackson has been elected honorary consulting physician to the Royal National Orthopædic Hospital and Dr. G. A. Sutherland, Mr. John Poland, and Mr. J. Jackson Clarke have been elected honorary physician, honorary surgeon, and honorary surgeon respectively. The new building operations have been begun and a hospital for 213 in-patients is being built on the site of the old hospital and the adjoining premises. The new out-patient department is to be separated from the hospital and will be on the opposite side of the road, on the east side of Bolsover-street, the hospital and the out-patient department being connected by a subway beneath Bolsover-street. Temporary accommodation for in-patients is provided in three of the vacant wards at Charing Cross Hospital which have been rented by the Royal National Orthopædic Hospital.

LEEDS INFECTIOUS *DISEASES HOSPITAL*, Seacroft.—Assistant Resident Medical Officer. Salary £150 per annum, with board, lodging, and attendance.

LEEDS UNION INFIRMARY, Beckett-street.—Assistant Medical Officer, unmarried. Salary £120 per annum, with board, washing, apartments, and attendance.

LESLIE, WOODILEE ASYLUM.—Junior Assistant Medical Officer. Salary £125 per annum, with board, washing, &c.

LINCOLN COUNTY HOSPITAL.—Junior House Surgeon, unmarried, for six months. Salary £50, with board, residence, and washing.

LISTER INSTITUTE OF PREVENTIVE MEDICINE.—Jenner Memorial Studentship. Value £150.

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Resident Pathologist and Registrar. Salary £100, with board and residence.

LONDON HOSPITAL, Whitechapel, E.—Surgeon-Dentist.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—Junior Resident Medical Officer. Salary £80 per annum, with board, residence, and laundry.

NORFOLK AND NORWICH HOSPITAL.—House Surgeon. Salary £80 per annum, with board, lodging, and washing. Also Two Assistant *House Surgeons for six months*. Salary £20, with board, lodging, and washing.

NORWICH, JENNY LIND INFIRMARY FOR CHILDREN, Unthank-road.—Resident Medical Officer (female). Salary £50 per annum, with board, residence, and laundry.

OXFORD, RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—House Surgeon, also Junior House Surgeon, both for six months, and unmarried. Salaries at rate of £80 and £40 per annum, with board, &c.

PERTH ROYAL INFIRMARY.—House Surgeon. Salary £60, with board.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Physician for six *months*, renewable. Salary £50, with board, residence, and *washing*.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Honorary Anæsthetist.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone road, N.W.—Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

ROTHERHAM HOSPITAL AND DISPENSARY.—Senior House Surgeon, also Assistant House Surgeon. Salary £110 and £80 per annum respectively, with rooms, commons, and washing.

ROYAL DENTAL HOSPITAL, Leicester-square, W.C.—Clinical Pathologist and Demonstrator on Bacteriology. Stipend £75 a year.

ROYAL EYE HOSPITAL, St. George's-circus, S.E.—Refraction Assistant. Salary £40 per annum. Also Clinical Assistants.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—Honorary Assistant Anæsthetist.

SALFORD UNION INFIRMARY, Hope, Pendleton.—Resident Medical Officer. Salary £130 *per annum, with apartments* and attendance.

STAFFORD, STAFFORDSHIRE COUNTY ASYLUM.—Assistant Medical Officer, unmarried. Salary £150, rising to £200, with apartments, board, and washing.

STOCKPORT INFIRMARY.—Assistant House and Visiting Surgeon. Salary £80 per annum, with board, washing, and residence.

STOKE-ON-TRENT, *NORTH STAFFORDSHIRE* INFIRMARY AND EYE HOSPITAL, Hartshill.—Junior House Surgeon. Salary £50 per annum, with board, apartments, and washing.

SUNDERLAND INFIRMARY.—*House* Physician and Pathologist, also House Surgeon. Salary in each case £80 per annum, with board, residence, and washing.

TAUNTON AND SOMERSET *HOSPITAL*, Taunton.—*House* Surgeon. Salary £100 per annum, with board, lodging, and laundry.

TUNBRIDGE WELLS GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, gas, firing, and attendance.

WEST BROMWICH DISTRICT HOSPITAL.—Senior House Surgeon, unmarried. Salary £110 per annum, *with*, board, residence, and laundry. Also Assistant House Surgeon, unmarried. Salary £75 per annum, with board, *residence*, and *laundry*.

WEST HAM INFIRMARY, Whipps Cross-road, Leytonstone, N.E.—Medical Superintendent. Salary at rate of £700 per annum, with house, light, and coal.

WESTERN GENERAL DISPENSARY, Marylebone-road, N.W.—Honorary Anæsthetist.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £120 a year, with board, lodging, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

DAY.—*On* July 12th, at Wetherby, Yorkshire, the wife of W. F. L. Day, M.B., B.C., M.R.C.S., L.R.C.P., of a son.

KEELING.—On July 12th, at Market Bosworth, Nuneaton, *the* wife *of* Hugh N. Keeling, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

NEWBOLT.—On July 15th, at 42, Catharine-street, Liverpool, the wife of George Palmerston Newbolt, F.R.C.S., of a daughter.

THOMPSON.—*On* July 16th, at 3, Park *Place*-gardens, Paddington, W., the wife of Dr. Peter Thompson, King's College, London, of a son.

MARRIAGE.

GLANVILLE—BELL.—On July 11th, at Hampstead Parish Church, by the Rev. Maurice E. Hoets, vicar of Weston, Bath, uncle of the bride, assisted by the Rev. Brook Deedes, vicar of the parish, William M. G. Glanville, M.B., B.Ch. Oxon., of Guyon House, Hampstead, elder son of the late Rev. J. F. M. Glanville and of Mrs. Glanville of Bristol, to Muriel, eldest daughter of Edward Bell of The Mount, Hampstead.

DEATH.

DUNSMURE.—On July 15th, at Queen-street, Edinburgh, James Dunsmure, M.D., LL.D., F.R.C.S E.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HORSE v. OX TONGUE.

THE medical officer of health of Stepney, Mr. D. L. Thomas, draws attention in a recent report to the fact that a horse's tongue is hardly *ever seen exposed for sale as cat's meat*. He *asks*, what *happens* to all the tongues of all the horses slaughtered in London every year. There should be no difficulty in distinguishing between the two, for the tongue of the ox has a narrow end and a rough upper surface, while that of the horse has a broad end and a smooth upper *surface. In our opinion it is quite possible that many of the* tongues sold as ox tongues are really those of the horse. If a tongue be boiled, pickled, smoked, and the outer epithelial surface be removed by scraping we doubt whether anyone could tell if it were that of the horse or the ox. The difference in the shape of the ends is easily concealed by pressing and rolling. We have never consciously eaten the tongue of a horse, but there is no reason why it should *not be just as good* as that of the ox, provided that both came from healthy animals. Substitution in food is a common trade deception. Thus, so-called turbot is frequently some other fish and in many cases the fish sold as whiting is really the whiting pout and not the silver whiting. The substitute is in this *last* case just as wholesome and of very nearly the same flavour, but in the case of the turbot no other fish has the same flavour. Nevertheless, the buyer should get what he asks for.

AN ETHICAL POINT.

To the Editors of THE LANCET.

SIRS,—I shall be glad if you will give me your ruling on this case, whether I acted in accordance with the ethical rule of the profession or not. A lady sent her maid to see me a few weeks ago. She was anæmic and had a history of amenorrhœa extending over a period of seven months. I asked if there was any chance of her being pregnant. This she with great warmth denied. I gave an aperient iron mixture and when seeing her mistress did not mention my suspicion. I stated she was being treated for the anæmia. Last week I was hurriedly summoned and found the lady from home and the maid in labour. When told her condition the maid said that it was quite impossible. I sent her home and now the mistress says it was my duty to mention my suspicion to her as she was paying the fee.

I am, Sirs, yours faithfully,

July 14th, 1907. M.D.

*** The duty of the medical man seems to us to be first towards his patient. We know the difficulty which arises when *applying* this rule in cases where an employer is the client and is paying the patient's fees, but we still consider that the rule holds good. We think M.D. would have been wrong to mention his suspicion.—ED. L.

A BLATANT ADVERTISEMENT.

WE have received from a medical correspondent a leaflet which he says was *handed in* at *his* house. This leaflet *sets out, in the regular* quack style, the accomplishments of a Mr. Halliday of Queen-street, Heckmondwike, thus: "Mr. H. being a Surgeon *Accoucheur*, Licentiate in Midwifery and Diseases of Women and Children of the Coombe Lying-in Hospital, Dublin, Dispensing Chemist, &c., &c., and *having been engaged* 33 years in the practice of Medicine by Botanic Remedies, is enabled to perform a *cure* in very many cases when all other treatment has failed." "Mr. H." then proceeds *to ask the usual* questions of his kind about the symptoms of chronic dyspepsia. "Have you pain or wind on the stomach? Have you Sickness, Headache, Dizziness, Sour *Risings in the* Mouth after eating, with aching pains between the Shoulder Blades?" and so on. If Mr. Halliday is a Licentiate in Midwifery of the Coombe *Lying-in Hospital* of Dublin, the authorities of that institution had better point out to him that such advertisement is not *suitable*. If he declines to alter his ways they might consider *the advisability* of removing his name from the register of the hospital.

THE HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.

THERE has recently been a good deal of *discussion* between the staff and governors of the Hastings, St. Leonards, and East Sussex Hospital respecting the qualifications required for the office of physician to the hospital. Until recently the rule *regulating* the appointment ran: "No person shall be elected to the *office* of physician unless he be a Fellow, or Member by examination, of the Royal College of Physicians *of* London, Edinburgh, or Ireland, and be a graduate in medicine of one of the Universities of the United Kingdom, and be also duly registered under the 'Medical Acts.'" *Until* 1904 the same rule applied to the assistant physician, but a difficulty having then arisen in filling that office it was agreed that a medical degree of the United Kingdom should be made a sufficient qualification for it. The matter was recently revived by the resignation of Dr. Frederick Bagshawe after 35 years' service, when there was found to be no active *practitioner* in the town with the necessary qualification for the post of physician. The whole of the hospital a usual hanging-drop preparation; but the coverslip is now pressed down evenly and gently on the yielding vaseline until the lowest surface of the hanging drop touches the upper surface of the glass slide below it. There is thus formed a column of blood touching both the slide and the coverslip. Round this column on the under surface of the coverslip a clear zone of extreme tenuity and about a millimetre in breadth will be found. So shallow is the blood here that leucocytes and clusters of blood plates cannot get past it, while the red corpuscles can only squeeze through gradually. The cells are therefore spread out in this zone as perfectly as in any ordinary liquid or dry film, but only by adhesion to the glass, while, as the cell is air-tight, drying does not occur for hours. Moreover, the zone acts as a kind of filter for the leucocytes, which will be seen in hundreds adhering living to the glass and still kept moist with serum. For staining, the blood may be mixed beforehand with a solution of some stain, or, perhaps better, with a few small particles of the undissolved stain. Exquisite pictures of all the elements can thus be obtained without any flattening by pressure.

Specimens made by these methods are, of course, not permanent, as the elements soon break up. But by mixing the solution of stain used for Method I. with glycerine or Farrant's preservative the preparations will last in fair condition (enough, for example, to show the chromolinin granulation of the red corpuscles) for some months. For good permanent preparations, however, more complex methods must apparently be used, such as that of Walker, described in the paper already referred to.[7]

A CASE OF CEREBRO-SPINAL MENINGITIS; ISOLATION OF THE SPECIFIC ORGANISM; PREPARATION OF A VACCINE; RECOVERY.

BY C. RUNDLE, M.D. LOND., M.R.C.S. ENG., AND
J. C. MOTTRAM, M.B. LOND., M.R.C.S. ENG.,
OF THE NEW CITY HOSPITAL, LIVERPOOL
AND
R. STENHOUSE WILLIAMS, M.B., C.M. EDIN.,
J. ORR, L.R.C.P. EDIN., AND A. E. WILLIAMS, M.D. EDIN.,
OF THE HYGIENIC LABORATORIES, UNIVERSITY OF LIVERPOOL.

THE patient, a male child, aged six months, was admitted to the City Hospital, Fazakerley, Liverpool, on Feb. 27th, 1907, certified to be suffering from cerebro-spinal fever. The diagnosis having been verified a vaccine treatment was decided upon, with results which seem sufficiently noteworthy to justify a report upon the clinical manifestations and course of treatment.

History of onset.—The child is stated to have been taken suddenly ill a fortnight before admission to hospital with vomiting and convulsions. Retraction of the head and neck was observed four days subsequently and squint within a week. Emaciation had been sufficiently marked to attract the attention of the mother within ten days of onset.

Condition on admission.—The general nutrition was fair, but loose folds of skin about the arms and thighs pointed to some recent wasting. The skin was pale and dry, presenting no rash. Beyond a few scattered râles no physical signs of disease were observed in the lungs; respiration was normal in character and frequency. The pulse was of fair tension, regular, and of normal frequency. Vomiting, a marked feature of the initial illness, had ceased; nourishment was taken readily and without difficulty. The general appearance and attitude of the child pointed to a profound disturbance of the nervous system. He lay on his side with his elbows and knees flexed, screamed shrilly at intervals, whilst his expression bore evidence of recurrent attacks of pain. The motor symptoms were definite and characteristic. The head was slightly extended on the spine and attempts to flex it were firmly resisted. The cervical and dorsal spines were fixed rigidly in orthotonos. The erector muscles of the spine were contracted and prominent with disappearance of the spinous processes between them. There was no trismus. The upper extremities were flexed at the elbows and the knees were drawn up upon the abdomen. These rigidities were tonic and not the result of an involuntary effort to resist movement. No clonic spasms or convulsions were observed. Double internal strabismus was marked and constant. Deglutition was unaffected. The age of the child precluded an accurate record of sensory impressions. Hyperæsthesia of the joints and skin was very marked. A light touch on the skin of the abdomen was sufficient to produce a scream of pain. No areas of anæsthesia were observed. There was no intolerance of ordinary daylight but the electric light called forth an immediate expression of pain. Similarly, although ordinary sounds produced little effect, loud noises, such as a clapping of the hands, caused obvious distress. No marked changes in the superficial or deep reflexes were observed. Kernig's sign was present but Babinski's sign was absent. The knee-jerks were slightly exaggerated. From the time of admission to the commencement of the vaccine treatment on March 11th the condition of the child became progressively worse. The general nutrition failed rapidly until no subcutaneous fat could be detected on pinching the skin. Spasm of the muscles of deglutition was induced by each attempt to swallow and the extreme retraction of the head and neck appeared to offer a physical obstruction to the passage of food. The contraction of the erector muscles of the spine produced a complete tetanoid opisthotonos. The elbows, hips, knees, and ankles became rigidly flexed, and the eyes fixed and staring. The pupils remained equal and active throughout. No paralyses or areas of anæsthesia were observed. Variations in the quality and timing of the pulse occurred, but retardation was never a marked feature. From March 9th to 11th vomiting recurred repeatedly and rectal feeding was resorted to. During this period the presence of the diplococcus intracellularis meningitidis had been detected in the cerebro-spinal fluid repeatedly, but lumbar puncture produced no alleviation of the irritative phenomena.

The first vaccine inoculation was made on March 11th. With the exception of a remission in the temperature of the body no marked change was observed in the clinical manifestations during the succeeding 48 hours. On the 14th, however, a definite decrease in the degree of extension of the head and neck was noted, the spine could be straightened with the exercise of moderate force, and lateral movements of the head were made voluntarily. On the evening of the 14th an exacerbation of the pyrexia occurred, not accompanied by an aggravation of the irritative phenomena. A second inoculation was made on the 16th followed by a period of apyrexia lasting 24 hours. On the 17th the eyeballs were observed to be fixed less rigidly, some lateral movements occurred voluntarily. The improved position of the head and neck at this period made feeding by the mouth again possible. Vomiting ceased entirely. Hyperæsthesia and Kernig's sign persisted. During the period from the 17th to the 21st the temperature was raised and irregular; a third inoculation was made on the latter date, followed, as were the previous inoculations, by a period of apyrexia persisting on this occasion six days. The squint was now occasional only, the position of the head and neck approaching the normal, and the flexion of the joints of the extremities was easily overcome. A moderate degree of pyrexia from the 27th to the 29th was met by a further dose of vaccine on the latter day. The temperature subsequently remained normal until the end of treatment. Kernig's sign was first noted as absent on April 2nd. From this date to the conclusion of treatment a rapid and progressive improvement in the condition of the child was maintained. The irritative phenomena and hyperæsthesia disappeared. The appetite and state of nutrition became normal. No affection of the special senses persists.

Our investigations into the efficacy of vaccine treatment in this disease have been restricted by the freedom of the city of Liverpool from cerebro-spinal fever in epidemic form, but there are, we think, some encouraging features in the history of this case and its treatment. The patient came under treatment at a time when his condition justified a most unfavourable prognosis. The extreme and progressive retraction of the head and neck, accompanied by other advanced nervous phenomena, the return of the vomiting (a most grave symptom), and the rapid emaciation pointed to the probability of a fatal termination. The apyrexia following the first injection of vaccine recurred after subsequent injections. So rapid and complete a recovery with no definite relapses or involvement of the special senses could, we think, scarcely have been expected with the customary methods of treatment at our disposal.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1907, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in THE LANCET of July 6th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1907 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

METEOROLOGICAL READINGS.

(*Taken daily at 8.30 a.m. by Steward's Instruments.*)

During the week marked copies of the following newspapers have been received:—*Evening Chronicle (Newcastle-on-Tyne), Rochdale Observer, Surrey Advertiser, Yorkshire Post, Herefordshire Mercury, Reading Mercury and Oxford Gazette, Newcastle Daily Chronicle, Manchester Guardian, Manchester Dispatch, Hull Mail, Manchester Chronicle, Daily Telegraph, Wimbledon Gazette, Hertfordshire Mercury, Army and Navy Gazette, John Bull, Westminster Gazette, Glasgow Evening Times, Glasgow Herald, &c.*

In this connexion one observation was made which is of interest in that it affects the specificity of the reaction. The blood of a patient suffering from scarlet fever (twenty-third day of disease, severe case, no complications) agglutinated the Liverpool strain in dilutions 1 in 20 (45 minutes); 1 in 50 (60 minutes); and 1 in 100 (neg., 75 minutes). Further investigations in this subject are being made.

D.—To test the identity of the Liverpool strain by comparing the effect of the patient's serum upon strains derived from other sources with its effect upon the Liverpool strain. For the cultures used we are indebted to Dr. Buchanan and Professor W. St. Clair Symmers.

Day of disease.	Source of culture.	Dilutions.		
		1 in 50.	1 in 100.	1 in 500.

58	Glasgow (B——).	32 „	40 „	Neg. 60 „
61	Glasgow.	27 „	Neg. 60 „	—

Löffler's methylene blue, as the latter failed to stain the degenerated forms, of which, except in very young cultures, large numbers were present. Gram's method was invariably negative.

Morphology.—Cocci, diplococci, and tetrads; no tendency to chain formation even in fluid media; there was much variation in size, the greater breadth compared with the length was a marked feature. The adjacent surfaces of the diplococci were flattened.

Reactions in carbohydrate media.—Medium employed: Lemco, 1 gramme; peptone, 1 gramme; sodium-bicarbonate, 0·1 gramme; carbohydrate, 1 gramme; 10 per cent. watery solution litmus, 10 cubic centimetres; ascitic fluid, 10 cubic centimetres; and distilled water to 100 cubic centimetres. Boiled for 20 minutes, 10 cubic centimetres filtered into sterile test tubes, and sterilised in Koch's steam steriliser for 20 minutes on three consecutive days. The tubes were inoculated from 24-hours old "nasgar" cultures and incubated at 37° C. for seven days. Films were made at intervals to test for possible contamination; on the seventh day "nasgar" tubes were inoculated from the carbohydrate cultures and gave a typical growth. The following table represents the changes that occurred:—

TABLE SHOWING THE CULTURE REACTIONS OF THE MENINGOCOCCUS ON CARBOHYDRATE MEDIA.

Origin of organism.	Maltose.		Glucose.		Galactose.		Saccharose.		Raffinose.		Inulin.		Salicin.

Glasgow (Briggs)	+	++	+	++	+	++	–	–	–	–	–	–	–	–
Belfast...	+	++	+	++	+	++	–	–	–	–	–	–	–	–

+ Indicates the first day on which a change of colour was noticed; ++ indicates the maximum reaction (a distinct reddening); and – denotes absence of reaction.

The table shows that the serum of our patient agglutinated all the strains available in the same dilutions as the Liverpool strain.

E.—Experiments to test the power of the patient's serum upon other organisms; for these the typhoid bacillus, bacillus coli, pneumococcus, and a streptococcus derived from a human throat were used. The typhoid bacillus, bacillus coli, and pneumococcus showed no agglutination even in dilutions of 1 in 10 (time, one hour). The streptococcus showed no agglutination in 23 hours incubated at 32° C.; dilution 1 in 10.

These experiments show that the agglutination reaction is not strictly specific, since both normal serum and the serum of a patient suffering from another disease produced it.

Identification of organism.—The cerebro-spinal fluid was obtained on March 1st (sixteenth day of the disease); films were stained but we were unable to satisfy ourselves of the presence of a bacterium. Tubes of Löffler's blood serum and ascitic fluid broth (1 : 2) were inoculated and incubated at 37° C. On the following day a pure growth of a coccus was observed on the blood serum tubes and occasional large cocci were found in the ascitic fluid broth; sub-cultures were made on human blood agar, Löffler's blood serum, and nasgar. In the early stages Löffler's blood serum gave the best results; it is of importance that it should not be overheated or dry.

Appearance of 24-hours old "nasgar" growth.—Smooth, greyish-white, moist-looking. On attempting to remove some of the culture with platinum needle distinct "stickiness" is noted.

Staining reaction.—The coccus stained with the usual aniline dyes; weak carbol-fuchsin gave better results than

Anaerobic cultures on "nasgar" by the pyrogallic method incubated at 37° C. were negative. Aerobic cultures on "nasgar" incubated at 20° C. also were negative.

We believe that the clinical features of the case, the morphology, the staining reactions, and the agglutination reactions compared with those obtained with meningococci from other sources, the changes in the carbohydrate media, and the absence of growth in anaerobic cultures and in aerobic cultures at 20° C. justify us in presuming that we were dealing with the diplococcus intracellularis meningitidis. The animal reactions were not successful. A 24-hours old "nasgar" culture was inoculated by intravenous injection into a rabbit on March 16th; the animal was alive and well on April 24th. 0·5 cubic centimetre of the cerebro-spinal fluid was inoculated into the peritoneal cavity of a mouse on March 1st; the animal died three days later. It had shown no symptoms before death; after death we were unable to demonstrate the coccus either in films or by growth on media.

The report of Dr. M. H. Gordon to the Local Government Board has been of very great assistance to us in this work.

Liverpool.

LITERARY INTELLIGENCE. — Messrs. W. B. Saunders Company have in the press, and will publish at an early date, a new work dealing with "The Pancreas, its Surgery and Pathology," by Mr. A. W. Mayo Robson and Dr. P. J. Cammidge, incorporating the results of the original investigations of the authors. The progress made within recent years in the knowledge of the functions and diseases of the pancreas has been so rapid that a book dealing with this important organ will be welcome.

The Croonian Lectures

ON

PLAGUE.

Delivered before the Royal College of Physicians of London on June 18th, 20th, 25th, and 27th, 1907.

By W. J. R. SIMPSON, M.D. ABERD., F.R.C.P. LOND.,
PROFESSOR OF HYGIENE AT KING'S COLLEGE, LONDON; GOVERNMENT COMMISSIONER TO INQUIRE INTO CAUSES AND CONTINUANCE OF PLAGUE IN HONG-KONG, 1902, 1903.

LECTURE IV.[1]

Delivered on June 27th.

NO SPECIFIC TREATMENT FOR PLAGUE.

MR. PRESIDENT AND FELLOWS,—I shall not touch on the specific treatment of plague. Great expectations were raised on the introduction of Yersin's serum but they have not been realised and a serum has yet to be discovered which, while being germicidal in its action, also possesses antitoxic properties. The researches of the late Dr. Allan Macfadyen were directed to the preparation of a serum with these double properties, but his untimely death at a moment when he appeared to be on the verge of success has postponed an early solution of this problem, though the researches have, I think, shown the direction in which the solution lies.

CONSIDERATIONS RELATING TO PREVENTIVE MEASURES IN THE PAST.

From the historical part of these lectures it will have been gathered that the discovery of a prophylactic by Haffkine gives the only measure of defence against plague that has not been employed more or less by some authorities in the older epidemics. Isolation of the sick, evacuation of the infected house, and segregation of contacts, disinfection, destruction of animals, and *cordons sanitaires* were employed. Quarantine of ships from infected ports and purification of merchandise according to the methods known at the time were also put into force. How frequently they were successful there are no means of knowing, but the numerous epidemics with the large mortality recorded are evidences of their failure in a large number of instances. The failure was caused mainly by the uncertainty of diagnosis with its attendant delays until the epidemic had become established and by the employment of an improvised and untrained service to deal with the disease. Deficiencies in organisation were attempted to be made up for by stringency and severity in rules. Thus at Windsor in the time of Queen Elizabeth, in order to protect the Court, a gallows was erected in the market place to hang everyone who came from London or brought wares from there during the epidemic of plague. In 1585 three gibbets were erected in different parts of Aberdeen "in case any infected person arrive or repair by sea or land to this burgh, or in case any indweller of this burgh receive, house or harbour, or give meat or drink to the infected person or persons the man be hanged and the woman drowned." These are echoes of the stringent measures taken by Visconti Barnabo in the fourteenth century to prevent people from plague-stricken places entering his territories. In Europe when plague prevailed the services of medical men as advisers and attendants on the sick were understood and taken full advantage of, but their services as authorities directing and controlling with special knowledge and machinery the fight against epidemic disease were not known. The idea is a product of the Victorian era, and it is not to be forgotten that the impetus for modern preventive work in medicine both for Europe and for India owes its source to England. In India the idea has developed more slowly than in Europe, the conditions there being less favourable to rapid progress. It began in the appointment of sanitary commissioners to provinces, a sanitary commissioner for the Government of India, and health officers to large towns such as Calcutta and Bombay, and the making of the civil surgeons *ex-officio* health officers of the station and district to which they were attached.

The Indian Medical Service, which does magnificent work in India, is very limited in numbers and being spread over the whole of India has a very scattered distribution. Duties military and civil have been assigned to it, and among the civil are attendance on Government officials, on the civil population, on the prisoners in the jails, on the inmates of the asylums, and on the patients in the local hospitals. Besides these duties the civil surgeon is expected to deal with vaccination and sanitation. There is also a small group of officers attached to the laboratories that are springing up in India. The Indian Medical Service being small and not having been increased proportionately to the increased duties which have been laid upon it by the authorities forgetful of the incident of the last straw on the camel's back, it is impossible, even if its strength were doubled and devoted wholly to preventive medicine, for such an establishment to deal with plague without being supplemented by a large and well-trained native service. There are 145 small towns in the Punjab alone.

It has been recognised for many years past by medical men in India who have paid attention to the subject that the sanitary organisation does not meet the wants of India and that great and fundamental changes are needed. The subject was publicly discussed in a paper read by me at the first medical congress in India held at Calcutta in 1894—i.e., nearly 13 years ago—and as a result of that discussion a deputation from the congress, headed by Surgeon-General E. Harvey, late director of the Indian Medical Service, who was a Fellow of this College, waited on the Government of India and pointed out the urgency and importance of providing a special sanitary service for India which should consist mainly of medical persons specially trained at the medical colleges of India in preventive medicine and which would open up an honourable and useful career in Government service for a number of the more ambitious and well-educated medical students attending the colleges in India. It was felt that just as there are a police service and a medical service there should be a separate and distinct sanitary service which should have its own budget. This was nearly two years before plague reached India, and the recommendation was based on the powerlessness of the system then existing to deal with preventable disease in India. The diseases then in view were cholera, malarial fever, and kala-azar. The appearance of plague in India accentuated the necessity for such a service and to its absence and the employment of improvised agencies consisting mostly of laymen may be partly ascribed a portion of the hostile attitude of the people and of the failure to deal with the disease.

In Europe in former times, in addition to the absence of any specially organised staff to deal with plague and the difficulty relating to diagnosis, there was also, as there always must be in every large epidemic, the difficulty of providing sufficient hospital accommodation for the sick and camps for those who had been in contact with the sick. Under stress of circumstances the fact which had been recognised at an earlier period that it was dangerous to shut up the sick with the healthy in an infected house was lost sight of and the practice came into vogue during the great epidemic in London to quarantine the house and household in an infected house. It was against this practice that in 1720 Dr. Richard Mead, a distinguished Fellow of this College, wrote when Europe had become alarmed by the severe epidemic of plague in Marseilles in that year. Dr. Mead advocated a return to the system which had been practised in Venice and Scotland since the sixteenth century—viz., the evacuation of infected houses, the sick being removed to hospital and the sound to special airy buildings outside the town. He recognised, however, that a time might come when the epidemic had increased to such an extent that this policy was impossible to carry out and that then, beyond fumigation of the house and attention to personal health, there was little to be done except forbidding convalescents to leave the house until a certain time had elapsed. To prevent infection being carried from an infected town to a healthy one he advocated the abolition of *cordons sanitaires* which the Marseilles authorities had adopted and which, owing to the food-supply being thus cut off, added greatly to the miseries of the population without any corresponding advantages. He proposed the substitution of a passport system after the person who came from the infected town had undergone quarantine or observation for a certain time and disinfection of goods.

MEASURES SHOULD BE DIRECTED AGAINST INFECTED PERSONS AND THINGS WITH THE OBJECT OF [illegible].

Writing against a system which favoured the spread of the disease from the sick to the healthy, Dr. Mead's

---

[1] Lectures I., II., and III. were published in THE LANCET of June 22nd (p. [illegible]), and July 6th (p. [illegible]) and 13th, 1907, p. [illegible], respectively.

No. [illegible]

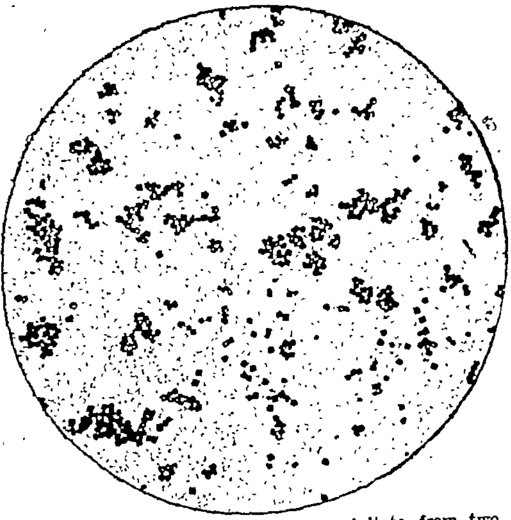
the precipitate is suspended in the liquid a sort of shot-silk appearance is produced from the admixture of red and blue, the precise character of the appearance varying according as the precipitate or the unchanged liquid preponderates, and likewise according to the position of the light by which it is viewed.

There is a point connected with the mode of applying heat to the test-tube that is worthy, I consider, of a passing comment. When the tube is heated in the usual manner from the bottom the normal coloured precipitate shows itself, whilst if heated by applying the flame to the top of the liquid and allowing the heat to travel down, the tube being held slantingly for the purpose, an ochry red precipitate is produced instead of the characteristic red otherwise obtained. The difference in the result produced by the two methods of heating is very striking and is found to apply to other instances where limited quantities of sugar are being dealt with.

I have spoken of the results noticeable after diminishing the sugar by a reduction of the amount of the solution employed, and it has to be said that no difference follows the diminution by the employment of more dilute solutions. The same character of precipitate is produced from the employment of a 1 per 1000 as from a 1 per cent. solution of dextrose. The same even is the case with a 1 per 10,000 solution, but here, on account of the smallness of the amount of precipitate, no effect is visible until after the test tube has stood for awhile for the particles of precipitate to settle to the bottom of the tube.

Examined by the microscope, the characteristic red precipitate I have referred to presents a certain typical appearance, no matter the precise manner in which it has been obtained. It is seen to consist of little nodular, more or less quadrilateral, masses which agglutinate or cohere together so as to form irregular-shaped collections. The cohering tendency of these nodules is a marked character belonging to them and the more they become grouped into compact masses the more is subsidence of the precipitate promoted. Fig. 1 gives a representation of the microscopic appearance of the precipitate under consideration and it may be remarked with regard to it that in the preparation of the slide a detachment of nodules occurs and renders the grouping less conspicuous.

FIG. 1.

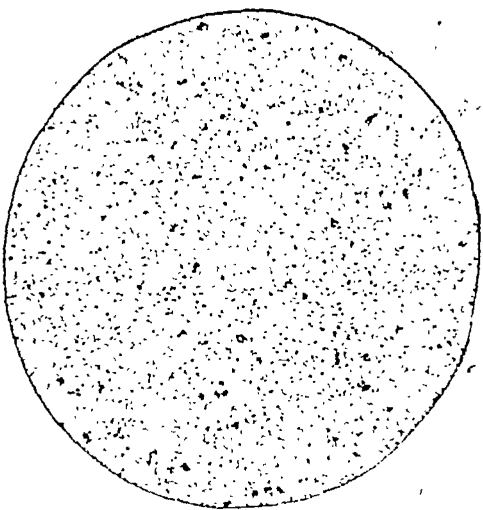


From photomicrograph of suboxide precipitate from two cubic centimetres of 3 per 1000 solution of dextrose and two cubic centimetres of Fehling's solution. Magnified 440 diameters.

If a reversal of the mode of procedure with a minimum quantity of sugar added to Fehling's solution be adopted and the 1 per cent. dextrose solution be placed in the tube and a minimum quantity of Fehling's solution be added an altogether different result is obtained. If, for instance, two cubic centimetres of a 1 per cent. solution of dextrose are placed in the tube and one drop of Fehling's solution added the effect on boiling is the production of a bright yellow precipitate which takes some hours thoroughly to settle out. If a relatively smaller quantity of Fehling's solution be used, as, for example, if four cubic centimetres of dextrose solution be treated with one drop of Fehling's solution, a paler yellow product presents itself with still less disposition to yield a settlement, and if eight cubic centimetres instead be the quantity taken a light canary-coloured liquid of a translucent nature is produced which even on the following day is found to contain suspended precipitate.

The microscopic appearance of the product yielded by the method of procedure just referred to differs in a very striking manner from that belonging to the previously described normal type of product. Taking the example of two cubic centimetres of sugar solution and one drop of Fehling's solution, instead of nodular masses being seen the precipitate presents the form of very fine particles exhibiting a tendency to link themselves into chains. Particles more appropriately define the condition seen than granules, and as the diminution of Fehling's solution in proportion to the dextrose solution is carried on further the particles become smaller and paler and finally cease to be within the reach of recognition by an ordinarily conducted microscopic examination; indeed, a sort of colloidal or emulsion-like condition is attained, both yellowness and translucency existing in much the same way as is sometimes observed with the reaction of urine containing a slight amount of sugar. Fig. 2 supplies a representation of the appearance presented.

FIG. 2.



From photomicrograph of suboxide precipitate from two cubic centimetres of 1 per cent. solution of dextrose and one drop of Fehling's solution. Magnified 440 diameters.

Increasing the strength of the dextrose solution has an effect that would hardly be likely to be predicted. With two cubic centimetres of a 25 per cent. solution of dextrose and one drop of Fehling's solution the precipitate produced on boiling is of a pale yellow, translucent, flocculent nature, presenting under the microscope the appearance of pellucid, spread-out plaques. With a 50 per cent. solution the result is attended with a greater appearance, both macroscopically and microscopically, of translucency.

It is thus seen that without bringing into the question the influence of any extraneous agency we can determine at will the production of modifications in the behaviour of sugar with Fehling's test resembling modifications that may be come across in the application of the test to urine containing a slightly abnormal amount of sugar. It is true the modification follows a method of applying the test different from that ordinarily adopted, but through the information obtainable by the aid of the microscope light is thrown upon the underlying condition existing which helps to give a clue to the solution of the problem before us.

MODIFYING INFLUENCE OF AMMONIA.

I will now deal with the modifying effect that is exerted on the action of the test when ammonia is present. The object in hand is to lead on to an explanation of the anomalous results that may happen to be observed in connexion with urine testing, and free ammonia is found to be developed as an attendant phenomenon of the proceeding.

It is well known that ammonia is a potent solvent of

It has been seriously advocated as a justification of the removal of all plague restrictions that the people, seeing the havoc that plague causes, would be willing to adopt for their own preservation European methods. The havoc has come but not the change in thought or habits of the people. Next comes the advocacy of rebuilding the huts and houses in the infected villages and towns of India, because it has been observed that the incidence was greater in dark, badly ventilated and rat-ridden mud huts than in others and particularly when they were grouped together in such a manner as to form a common tenement for large numbers of families. The scheme is a good one, which will be supported in principle by all sanitarians, but it is obvious that on a large scale the cost is prohibitive and even if the money were forthcoming could only be brought about after the lapse of very many years. In the meantime the people are dying.

The reluctance to be removed to hospital for purposes of segregation is a general one in every country but it is accentuated in the East by the fact that in consequence of the great mortality from plague very few patients taken to the hospital return to their homes. It is necessary to consider the dislike to removal to hospital from the standpoint of the patient and the patient's friends. I remember the difficulty as a rule encountered in getting either Hindu or Mahomedan to be removed to hospital when suffering from small-pox, which is not nearly so fatal a disease as plague. The compromise which had often to be made was to vaccinate everyone in the house and as far as possible in the adjoining houses, leaving the patient to be treated at home, and after death or recovery of the patient the disinfection of the house. A similar procedure is feasible in plague, except, as I shall show afterwards, the house should be disinfected at once. The impossibility of destroying during an epidemic all rats and fleas in a town or province has already been mentioned and measures have to be devised to concentrate the destruction where it will be most useful; liquid chemicals, except perhaps in the case of latrines and also for washing one's hands, are valueless and a waste of money. Possibly an exception may have to be made to this statement regarding pesterine, a preparation of petroleum employed by Dr. J. A. Turner, the health officer of Bombay, and which he has found useful for the destruction of fleas in rooms.

IT IS IMPOSSIBLE FOR THE PEOPLE THEMSELVES ON THEIR OWN INITIATIVE TO COMBAT PLAGUE.

Moreover, it is a fundamental point in any preventive measures in India to recognise the fact that it is impossible for the people themselves on their own initiative to defend themselves against the ravages of plague. One might as reasonably expect each village and town on its own initiative to defend itself against a powerful invading army. With the exception of a few large towns, such as Bombay and Calcutta, the general conditions prevailing in India and the relations of the Government to the people, which are of a paternal and patriarchal character, are opposed to any initiation or carrying out of measures by the people themselves *without direction*, supervision, and control by the Government. In 1902 the Gujrat district inhabited by Mahomedan agriculturists was seriously affected with plague. The Deputy Commissioner writes: "As a rule the people were extraordinarily patient while the disease was epidemic in the village. Their attitude was entirely that of quiescence. They were willing to take almost any steps they were advised to take so long as someone in authority was present to see it carried out, but if no one was there to see it carried out they let things go as they were before and did nothing." This may be stated to be the general attitude of *the* peasants and poorer people in India. For centuries the *Sircar* or Government has been looked up to for guidance and to be told to rely on themselves or anyone else besides the Sircar is not understood.

In 1903 Mr. Maynard, a Deputy Commissioner, in his report on plague operations in the Punjab says: "The measures authorised by the Government are now in some respects behind rather than in advance of what general opinion would approve. It must be realised that the people cannot altogether protect themselves A community that is not completely organised for self-government hardly knows what it wants and certainly cannot enforce its will without external help. It is not fair that it should be at the mercy of selfish or reckless individuals."

The resolution of March 9th, 1904, of the Government of the Punjab points out the unfriendly attitude of the inhabitants of infected villages as among the reasons for leaving measures to the people themselves. With reference to evacuation of infected houses it says: "It is by adopting this measure that the people can help themselves best. They must not, however, look to Government for assistance and establishment. It is out of the question to provide huts or extra police." And on the subject of killing rats it goes on to say: "It has now been decided that it is undesirable to incur any further expenditure on further experiments." This policy was reversed in April, 1907, in the adjoining province of the United Provinces when it was announced in the Legislative Council that the Government had determined to depart from the old policy and to provide shelters for the plague-stricken people who evacuate their homes, £2000 being devoted to that purpose and a special plague committee being appointed to advise as to the methods for fighting the disease and spending the sum mentioned.

It may be taken as an axiom that without a specially trained agency to direct and control the plague measures the essentials in regard to the prevention of the disease are forgotten or misapplied and often useless measures are adopted. Without this agency it is a matter of the blind leading the blind. It is pitiable to read some of the suggestions which are made to deal with plague and which are accepted and carried out in good faith as being likely to check the epidemic. Here an inspector is added to the conservancy staff, there it is a few bheesties or water-carriers, and elsewhere a native surgeon. They are all doubtless useful in their way but as regards influencing the plague the money spent on them is thrown away. Similarly when I was in Poona last year I learnt from the health officer that a sanitary engineer had visited the town with the object of drawing up a drainage scheme, which was an excellent thing in itself and which would cost much money, but it would have no effect on plague, which is the most serious illness from which Poona is suffering.

THE STATE OF POONA IN SEPTEMBER, 1906.

I consider the keynote of success to the prevention of plague is the provision of money and machinery and of a special plague organisation to direct, to supervise, and, if necessary, to carry out the requisite measures. With such a trained organisation, having yearly conferences to compare notes between the heads of departments, it would be possible to sustain and to carry out a settled policy modified only by scientific research and experience. This is what is needed for India and I shall illustrate the necessity for it by an instance which recently came under my observation when I was in India in September, 1906. At that time plague prevailed in Poona, a town of not more than 120,000 inhabitants. At the last census it numbered 110,000 persons. The town had already in its previous epidemics lost over 30,000 of its inhabitants. This fresh epidemic began with one death from plague in June, followed by 107 deaths in July, 1166 deaths in August, and 1173 deaths in the first 13 days of September. On the day I inspected the registers 90 deaths from plague had occurred before noon. By the time this epidemic was over another 8000 deaths were added, bringing up the total of all the epidemics to at least 40,000 deaths.

Under the guidance of Dr. Satpute, the municipal health officer, I visited the plague-stricken quarters of the town, and I shall never forget the painful impression produced on my mind by the heartrending scenes of distress, despair, and desolation which met me on every side. The town had the appearance of a deserted city. The streets were silent, some of them had scarcely an inhabitant visible in them; the only sounds which occasionally broke the silence as we passed through street after street were the noise and clang of the funeral processions and the wail and cries of the mourners at houses in which a death had recently occurred. In whole streets the shops and houses were closed and in those quarters where shops were open they were served by men who only remained in them during the day and left the city for the night. I visited house after house where deaths from plague were being treated by one or other of the two hospital assistants under the health officer. The patients lay in rooms and passages which were often so dark that it was with difficulty they could be seen. In the house where plague first broke out in 1906 the owner had lost his seven sons during the seven epidemics from which Poona has suffered. Similar tragedies belonged to *other houses*. These seven epidemics have impoverished the municipality, have destroyed an enormous number of people, have brought ruin and beggary to many families, and have increased the price and scarcity of labour. Falling on the adult population, the labourers have been chiefly affected. The ravages of the plague have, however, cuprous oxide, which coincides in microscopic appearance with the analogous precipitate produced by pure solutions of sugar. Weak potash solution may be used to dissolve the uric acid and a 3 per 1000 strength of the acid is a convenient one to employ to show its behaviour; but it should be understood that the reaction produced is not a large one. If too much uric acid is present a white precipitate falls which interferes with the occurrence of reduction. The same effects follow in the case of uric acid as a result of the presence of ammonia, albumin, and albumin and ammonia conjoined, as was mentioned to occur in the case of sugar. Particularising for the last, two cubic centimetres of 3 per 1000 uric acid, two cubic centimetres of Fehling's solution, five drops of 2 per cent. albumin solution, and five drops of ammonia give, after the very prolonged boiling required to get rid of the ammonia, the milky-green and greenish-yellow reaction that is often met with in testing urine.

The cupric oxide reducing power of uric acid is considerably less, reckoning weight for weight, than that of sugar. It is easy of determination by means of the ammoniated cupric (Pavy's) test. I some time ago suggested the employment of this test for the quantitative estimation of uric acid in urine. The subject was brought forward in a communication to the Royal Medical and Chirurgical Society and the communication was published in Vol. LXIII. of the Society's Transactions. The process consists of taking the reducing power of the urine before and after treatment with lead acetate, which is a precipitant of uric acid. From the difference the uric acid is calculated and the several results of actual observations given, in which known quantities of uric acid were dealt with, show that the process is capable of yielding estimations of very close accuracy. It must be admitted, however, that it is only in the hands of those possessing considerable experience and expertness that reliability can be expected to be attainable.

The actual cupric oxide reducing power of uric acid in relation to that of dextrose is less to the extent that 18·6 parts of uric acid stand as the co-equal of 10 of dextrose. This is deducible from the fact that whilst 10 milligrammes of dextrose constitute the reducing equivalent of 20 cubic centimetres of the ammoniated cupric test, it requires 18·6 milligrammes of uric acid to bring about a corresponding reducing effect. Hence not far from double the amount of uric acid is needed to produce the reducing effect that is capable of being exerted by dextrose.

I may mention that I have recently tested the accuracy of the results upon which the above statement is based by subjecting a specimen of uric acid procured from Kahlbaum of Berlin to examination. The results yielded stood in close accord with those previously obtained.

With the data at our command the portion of the reducing power of a specimen of normal urine which is to be ascribed to uric acid can be expressed in terms which may be considered to fall within a close reach of accuracy. Although it may not be indicated by Fehling's solution, urine, nevertheless, has always a certain measurable amount of cupric oxide reducing power, which, it may be said, is considerably greater than it is generally thought to be. This reducing power is readily susceptible of recognition and quantitative estimation by the ammoniated cupric test and in my recent work on "Carbohydrate Metabolism and Diabetes" I have given the results of numerous determinations of its amount in the urines of various animals, including man. Figures are given representing the condition found in 12 specimens of normal urine from the human subject. The highest of these stands at 4·88 per 1000 expressed as dextrose, and the lowest at 0·91, the mean of the 12 being 2·79. It may be remarked in passing that the amount found is largely dependent upon the degree of concentration of the urine under examination.

Taking the above mean figures we have 2·79 per 1000 standing as the average representative of the cupric oxide reducing power expressed as dextrose of the specimens of urine in question. What portion of this is due to uric acid? Let us see how the calculation works out under the following mode of dealing with the matter. It is ordinarily reckoned that about one gramme constitutes the quantity of uric acid and about 1500 cubic centimetres the quantity of urine eliminated per diem. One gramme in 1500 cubic centimetres gives 0·66 gramme as the proportionate amount in 1000 cubic centimetres. Of the total reducing action, consisting of 2·79 per 1000 expressed as dextrose, a portion is due not to dextrose, but to the 0·66 per 1000 of uric acid that is present. It has been shown above that 18·6 parts of uric acid correspond in reducing power with 10 parts of dextrose. From this relation the 0·66 gramme of uric acid will have a reducing power expressed as dextrose of $\frac{0\cdot66\times10}{18\cdot6}=0\cdot35$, which brings the issue to 0·35 part of the reducing power out of the 2·79 being due to uric acid. Otherwise expressed, about one-eighth of the reducing action of normal urine upon the basis formulated is attributable to the uric acid present.

I have spoken of the cupric oxide reducing power possessed by uric acid and it is only this that brings uric acid into relation with the subject under consideration. It has no influence on the reaction producible by sugar.

INFLUENCE OF CREATININE.

The action of creatinine in its reducing effect on Fehling's solution is not of the simple nature of the ordinary reducing bodies. It may be said at once that a complicated result is produced through its influence on the character of the precipitation and the generation and evolution of ammonia which, to a pronounced extent, takes place as an accompanying event. My observations have been conducted upon a specimen obtained from Merck of Darmstadt, a source which I think may be considered to justify confidence with respect to purity.

In the first place two cubic centimetres of a 0·5 per cent. creatinine solution (= ten milligrammes creatinine) were boiled and kept boiling, with careful agitation of the test tube to prevent ejection of its contents, with an equal quantity of Fehling's solution. The result was attended with the following succession of events. Ammonia in notable quantity began almost immediately to be evolved, as shown by litmus paper, corroborated by paper soaked in Nessler's mercuric iodide solution, introduced into the mouth of the test-tube, and was still being evolved when the boiling was stopped at the end of ten minutes. The blue colour first to some extent faded and then acquired a greenish tint, the liquid remaining bright and clear. Not till the boiling had been carried on for nine minutes was any turbidity perceptible, and then the contents of the tube became opaque and of a dirty green colour which afterwards passed into a yellowish green. After having stood for some time some yellow precipitate was seen to have settled out. A drop of the liquid examined microscopically at the end of the boiling displayed a field of very minute disconnected particles presenting a resemblance to the molecular base of chyle.

Increasing afterwards the creatinine by using a 2 per cent. strength of solution, the boiling failed to be attended with any show of reduced oxide. Ammonia was from the start very freely evolved. The blue soon changed to green, which faded and became replaced with a brownish tint that passed on to reddish-brown, ruby red, and deep brown, translucency all the time being maintained. After a quarter of an hour's boiling ammonia was still being evolved and nothing throughout was apparent that could be taken as representing a show of precipitation.

Creatinine, then, has an effect of a very different nature from that of an ordinary reducing body upon Fehling's solution, and the conclusion forces itself on the mind that ammonia is an important factor in connexion with what is noticed to occur. As long as sufficient ammonia is present to hold in solution the reduced oxide that is formed there can be no appearance of precipitate. With reduction fading of the blue colour of the test ensues and the conditions may be such as to determine a complete removal of colour, but no precipitate can fall as long as ammonia is being liberated to a sufficient extent to hold the generated suboxide in solution. Probably the motley series of colours observable after prolonged boiling, especially in the presence of a considerable quantity of creatinine, are due to extraneous decompositions that occur whilst the suboxide is being prevented from showing itself.

The cupric oxide reducing power of creatinine does not appear to amount to so much as what I find it has been credited to possess. There is no difficulty in making the estimation by means of the ammoniated cupric test. The solution titrates cleanly and the end-point is sufficiently sharp. Variations within certain limits are, however, noticeable in the readings, seemingly due to the rate at which the solution may be run in from the burette. If run in quickly time is apparently not given for the full breaking down of the creatinine and more is run in than might be needed if longer time were given. The results that have been obtained may be said to give to creatinine a reducing

Indian Medical Service, who took an active part in the inoculations, describes the attitude of the villagers in this respect. When he began to give the Amritzar people an account of the Mulkowal accident they said that they had seen for themselves the good effect of the inoculations and the sooner he stopped talking and began working the better they would be pleased. He soon finished the few doses he had with him and he remarks: "The genuineness of their feelings was evidenced by the reproaches of those who had to go away unsatisfied, the reproaches of some of the women taking the form of an abuse which was evidently heartfelt." However, with the Government averse to continuing any sustained effort, little or no further progress was made, and in 1904, when the plague was causing enormous ravages, only 49,000 persons were inoculated in the Punjab. It is stated in the report of the Inspector General of Civil Hospitals, who was in charge of the plague operations, that "no special measures were taken for inducing the people to submit to inoculation and the operation was performed almost solely in response to the spontaneous demands of the people." An attitude of this kind in a grave crisis is unjustifiable. In no country of the world can the peasant population be expected to form an opinion on the merits or utility of a scientific method, and even if its utility were appreciated by them, as appears to have been the case with the 49,000, the initiative and organisation required for providing that the full benefit of the measure shall be secured devolve upon the Government. There is no reason that Haffkine's great discovery should not again be made use of on a larger scale. If it finds favour with the Government to-day it will be in favour with the people to-morrow, but the organisation must be such that in its application in the villages there is not the slightest chance of another accident. I believe a pronouncement exonerating the laboratory would, in the circumstances in which it has been mistakenly blamed, have an excellent effect in reinstating the enthusiasm for inoculation.

There is no reason, moreover, that systematic endeavours should not be made whenever a case of plague occurs in a house to get the inmates of the house, and possibly those of the adjoining houses, to be inoculated, and if the benefits are thoroughly explained to them in their own language and tactfully Indians, like other people, are not averse to avail themselves of anything that is likely to be to their advantage so long as they believe in the honesty of those who are dealing with them. Necessarily, one comes across exceptions who will have none of it, but these sort of people are not confined to India. Inoculation is the cheapest mode of protection. The cost of vaccines, establishment, and equipment works out to less than 6 annas per person inoculated, which is not an excessive expenditure. Owing to the original Punjab scheme being abandoned the cost was slightly over 1 rupee a head on the 500,000 inoculated, but if the numbers contemplated—viz., 7,000,000—had been inoculated it would have cost about 1½ annas, or about 1½d., per head. The margin of 6 annas per head will therefore be seen to be liberal.

Evacuation of an infected locality and inoculation promptly carried out will stop any epidemic. In Cape Town plague was becoming serious among the Kaffirs. It was decided to remove them from their dwellings where they were crowded together under most insanitary conditions as bad as, if not worse than, any in India. In the course of a week from 7000 to 8000 were removed to a small village prepared for them and all were inoculated. The epidemic ceased among them and although after two or three days' rest in order that they should recover from the malaise caused by the inoculation they came in regularly to Cape Town and often worked in infected portions of the town they remained free from the disease.

In an infected area the measures to be adopted are controlled to some extent by circumstances. In some localities all the measures mentioned can be brought to bear and of course these are the best conditions for success. But if plague is in a village where there are no means of disinfecting the huts and destroying the rats during the process of disinfection, then evacuation and inoculation are the only measures that can be practised, and if inoculation is carried out the evacuation need only be as long as is necessary to allow of time for the inoculations. Exposure of the grain to the sun, boiling the infected clothes, general destruction of rats, and a general use of pesterine, as advocated by Dr. J. A. Turner, the health officer of Bombay, should also be carried out. In towns where it is possible to carry out disinfection the complicated and unsatisfactory methods belonging to the systems now in vogue should be abolished. When dealing with an epidemic I know of nothing which is more irritating to householders, rich or poor, and which contributes in a greater degree to the hostility met with in disinfecting many houses and to the fostering of surreptitious removal of infected clothing than the fact that everything suspected has to be removed to a central station for disinfection by steam, that the furniture and house have to be sprayed and washed with disinfectants, and that the inmates of the house are turned out for nearly a fortnight before they can get back again. It is exceptional if during the several procedures some articles are not lost or spoilt. At the end of the disinfection, even with careful work, insects will often be seen in the tropics to survive, while the process has no effect on the rats or the rat runs. For these reasons I would abandon all disinfection of this kind and substitute a system of fumigation by a gas which shall disinfect everything *in situ*, which shall, in addition to destroying the germs of the disease, kill the fleas, bugs, other insects, and rats, and which shall disinfect the rat runs in the house.

The Clayton method of disinfection, which consists in the pumping of sulphurous acid gas with sulphuric anhydride into the house, destroys not only the plague germ but all rats, fleas, bugs, and other insects in the house, and it can be applied to thatched huts with the same effect. The gas is generated by burning sulphur at a high temperature in a specially constructed portable apparatus which is brought to the front or back of the house and which is not unlike the vacuum carpet cleaners. One pipe from the apparatus conveys the sulphurous acid gas previously cooled down to a normal temperature into the house, and another pipe also connected with the apparatus draws the air out of the house and through the furnace. Gradually the air in the house becomes saturated with sulphurous acid gas and it has been established that a few hours' exposure to a 2 per cent. gas in the different rooms is destructive to insects, rats, and the plague germs. Not more than seven hours would be required for each operation. The advantages of this method of disinfection are that no occupant of a house need evacuate the house for more than 24 hours at the most, that no furniture, bedding, nor clothes require to be removed from the house, so that there is no risk of the articles being mislaid or stolen. Everything is disinfected *in situ;* the only articles that require to be removed are such foodstuffs as flour, fresh fruits, fish, and meat. Rice and grain need not be removed and would be disinfected along with the other contents of the house. As rice and grain are the most common foodstuffs and the most liable to be contaminated by infection their disinfection is most important. Any discolouration of exposed metal or silk-stuffs can be immediately removed by a weak solution of ammonia without any damage whatever, and a very important fact in connexion with this mode of disinfection is that even such things as become tarnished by direct exposure to the gas are unaffected when they are covered with cloths or are in closed boxes and yet they are disinfected. The gas also has a certain penetrative power into the soil. As stated previously, the disinfection is as applicable to huts with thatched roofs as to houses and more than one series of pipes can be attached to one machine and blocks of houses can be disinfected with several machines in such a manner that the rats, old and young, are prevented from migrating from these blocks and so get destroyed and the infected rat runs are also disinfected. In the case of a plague patient being in the house and objections being raised to removal to hospital the patient can be made comfortable in a tent during the fumigation and be removed back to the house after 24 hours, for with the rats and insects destroyed there would be little danger of the spread of the disease. After the patient had recovered or died the house could be again disinfected.

How to Prevent Recrudescence at Poona.

From a practical point of view it might be asked what can be done with Poona, which has had 40,000 of its inhabitants die from plague since 1896 and which suffers from plague nearly every year. The town is being ruined and is there nothing that can be done to save it? I believe that if measures were taken on a sufficiently large scale and on an organised plan it is possible to rid Poona of its recrudescent plague, and when this is done then imported plague might with care be kept fully under control. For thought it unnecessary. The pleura was congested and the pleural cavity contained more serous fluid than natural. The lungs were dark and markedly congested. With regard to the pericardium the cavity contained more serous fluid than normal. The heart was slightly enlarged and the valves were healthy. Ante-mortem clot was present. As to the abdomen, the peritoneum was congested and spotted all over with black spots of various sizes and different shapes. There was more serous fluid than normal in the pelvic cavity. The uterus extended up close to the xiphoid cartilage of the sternum and corresponded with a uterus at full term. The peritoneum over it was congested and contained dark spots. On opening the uterus a full-term male child was removed; it was a well-developed, healthy-looking infant; the skin was healthy and without any spots or marks of any kind. The placenta, membranes, and cord were normal in size and appearance. The mesenteric glands were congested, which has been shown lately in Germany to be important from a diagnostic point of view, a view confirmed by Professor W. St. C. Symmers of Belfast. The liver was enlarged and full of blood. The gall-bladder was full of bile and the coating of the bladder was covered with dark spots. The spleen was enlarged and full of blood. The kidneys and suprarenal capsules were congested. The pancreas was congested. The stomach contained a little food with some dark grumous matter which was evidently the medicine prescribed that morning. There were dark spots over the mucous surface, which was also congested. The small and large intestines were congested and almost empty; Peyer's patches were congested and the walls of the intestines were spotted. The bladder was empty and on opening it the mucous surface was covered over the whole surface with small dark spots. As this case occurred in the earlier stage of the epidemic I regret bacteriological examinations were not made.

THE TREATMENT OF TRYPANOSOMIASIS.[1]

BY A. NIERENSTEIN, PH.D.,

OF THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

THE therapeutics of the present time for trypanosomiasis can be divided into the following.

A. Arsenic compounds.—1. Arsenious acid. 2. Fowler's solution.

B. Colours.—1. Colouring matters belonging to the diazo group, Ehrlich's trypanred and Mesnil's afrodol blue and afrodol violet. 2. Colouring matters belonging to the triphenyl-methan group, Ehrlich's malachite green and fuchsin.

C. Atoxyl, which being an organic compound of aniline and arsenious acid cannot be considered as merely "an arsenic compound," an expression recently used in the lay press.

The introduction of an acid radicle into an amido nucleus generally changes its basic character and of course, on the other hand, lessens the acidity. The combined effect of aniline and arsenic is therefore the resultant of these two factors: amido group and arsenious acid. We have been able to demonstrate experimentally that either the amount of aniline generally given in the form of atoxyl or the arsenious acid contained in that drug when administered alone will kill an animal within a few hours after the injection.

D. Combined treatment.—1. Combination of arsenious or acid atoxyl with colouring matters, as trypanred suggested by Thomas and Breinl, Laveran and Mesnil, and others. 2. Atoxyl and strychnine—van Campenhout. 3. Atoxyl and sublimate. The last-named treatment has recently been worked out in the Liverpool School of Tropical Medicine and the results obtained on rats are very promising.

We who have been working in the Liverpool School of Tropical Medicine found that in infected rats (Trypanosoma Brucei), one part of which were treated with atoxyl alone and the remainder with atoxyl followed by mercury, the first lot generally had relapses in from 16 to 25 days, while a great number of the animals treated with atoxyl and mercury are still alive, some after a period of nine months. These results are certainly encouraging. In our treatment we used, at the beginning, to give high doses of atoxyl in order to drive out the parasites entirely and it was found that if sufficient atoxyl were administered the parasites (Trypanosoma Brucei) would disappear in rats for from 16 to 25 days. A disappearance of the parasites for a similar period was also observed in guinea-pigs and rabbits. Mercury was then given and the treatment stopped. In the bigger animals this double treatment should be continued for some time.

With regard to sleeping sickness we would like to suggest as a routine treatment that one cubic centimetre of a 20 per cent. solution of atoxyl should be given daily for one week, followed by one cubic centimetre of a 1 per cent. solution of sublimate four times. This treatment should be repeated and continued for an extended period and, of course, may require occasional modification. It would perhaps be possible to give mercury in the form of pills. The theory of the action of mercury in this treatment has been discussed in a paper published in the Annals of Tropical Medicine and Parasitology of the Liverpool School of Tropical Medicine, Vol. I., No. 2.

It has been found that the toxic effect of atoxyl can be diminished by acetylating the atoxyl. Such an acetylated atoxyl is an antipyrine which contains arsenious acid. Acetylated atoxyl has been shown to be of use in mice by Ehrlich and in dogs by our experiments. We found, as a rule, that when atoxyl was given in a sufficient quantity to drive out the parasites (nagana) in dogs the host was also killed, but using acetylated atoxyl we have been more or less successful. An interesting fact, pointed out by Ehrlich, is that the parasites can get used to a drug and become resistant. It is therefore advisable to alternate various trypanocidal agents in the treatment as much as possible, that is, to give atoxyl, some other trypanosome-killing drug, and mercury; for example, atoxyl, fuchsin, or some other colouring matter by the mouth, and sublimate.

It has usually been recommended to give atoxyl in high doses at the beginning. Whether or not this is of benefit is a question, as the atoxyl apparently accumulates in the body and the toxic effect appears after a time. In laboratory experiments we have frequently noticed that even after the treatment had been stopped for a week toxic effects appeared and this could only be due to the fact that atoxyl had accumulated in the body and the arsenic had been slowly broken up. We would like to refer to one experiment; a rat was treated about nine months ago with atoxyl and is still showing toxic effects.

We think it necessary to point out that the administration of atoxyl should be given a very careful trial but that extremely high doses should be avoided as much as possible. The action of atoxyl seems to be very much on the nervous system, as neuritis is frequently caused by the administration of this drug. Blindness has also been observed after the use of atoxyl and the question therefore arises whether it would not be well to counteract somewhat the effect of atoxyl by making it less operative on the brain and nerves. This might be done by introducing radicles which are more fixed to the blood and less to the nervous system.

We think it necessary to draw attention to experiments which we have made in connexion with the reappearance of trypanosomes after treatment with atoxyl. We found that strains obtained from animals which had had relapses were sometimes much more virulent. Our nagana strain, used for work generally, killed a rat in from five to seven days. This strain was followed up, commencing on Jan. 14th, until May 5th by subinoculation from one rat to another; four drops of blood were always used. In none of these rats was any sudden increase of virulence noticed, but in experiments with the strain obtained from animals in which the trypanosomes had reappeared it was found that the experimental animal was killed in from three to five days. Out of 17 rats used for these experiments 11 showed a remarkable increase of virulence. Similar work done with Trypanosoma dimorphon showed the same increase of virulence. Our strain used to kill a rat in from 15 to 17 days and we found that in four out of six strains obtained through relapses after treatment by atoxyl the virulence obtained was from 11 to nine days. We have recently obtained through atoxyl a Trypanosoma dimorphon strain which kills a rat in seven days. Similar work with Trypanosoma Gambiense is now in progress.

It was our intention not to publish the results of this work until we had satisfied ourselves that Trypanosoma Gambiense behaves in a similar way, but since it is intended to commence atoxyl treatment on a large scale in Uganda we feel that a warning in this direction should be given.

These observations emphasise the necessity for careful who have smoked or drunk to excess, are also more liable than others to reflex respiratory derangement. Healthy patients with good cardiac action, although more likely than old and feeble subjects to display this form of surgical shock, are better able than the latter to hold out against the strain which it imposes upon the circulation. Respiratory shock may be met with under all anæsthetics but it is perhaps more prone to arise when the anæsthetic is one which itself throws some strain upon respiration. The degree of anæsthesia which is most favourable to the occurrence of respiratory shock is undoubtedly a light or moderate degree. Reflex respiratory disturbance is rare when full anæsthesia has been secured, although cases occasionally occur in which reflex tongue retraction causing stertor and particularly reflex laryngeal spasm causing stridor arise even though the corneæ are completely insensitive. The operations which are most likely to induce the condition under consideration are those upon the rectum and genito-urinary organs, and those within the abdominal cavity. The dilatation of the sphincter ani of a muscular man whose corneal reflex has not yet disappeared is almost always attended by some degree of respiratory embarrassment due to reflex tongue retraction, or laryngeal spasm, or both. Skin incisions, the wrenching of stiff and painful joints, and the passage of a catheter may also be given as examples of procedures which may, in favourable circumstances, bring about reflex respiratory arrest. The phenomena which lead up to respiratory shock usually occur in the following order. (1) There is a more or less sudden alteration in respiration due to muscular spasm within or about the respiratory passages and usually, though not necessarily, characterised by stertor or stridor; there is consequently (2) a more or less sudden diminution in the quantity of air entering the lungs which rapidly leads to (3) lividity or cyanosis. In certain cases the asphyxial state thus set up quickly leads to (4) venous engorgement and swelling of the tongue, fauces, palate, and adjacent structures, so that the obstruction becomes intensified. Finally, if respiration be not re-established pallor, pulselessness, and death ensue, the rapidity with which the case thus terminates depending upon the particular anæsthetic employed, the degree of anæsthesia at the moment of the seizure, and the state of the patient's cardio-vascular system. Cases frequently occur in practice in which some surgical procedure—e.g., persistent peritoneal manipulation—keeps up persistent laryngeal spasm as evidenced by the persistent stridor, and as the result of this spasm the patient's condition very materially suffers, the *face becoming* increasingly dusky and pale and the pulse feebler and feebler. I need not give you examples of cases of this class. They are by no means uncommon, but they are very frequently misinterpreted and the unfavourable symptoms wholly ascribed to the anæsthetic. The character of the phenomena in any given case will vary with the circumstances present—the type of subject, the state of his upper air passages, the stage of anæsthesia, the nature of the procedure, and other factors.

---

[1] A paper read before the Society of Tropical Medicine and Hygiene on July 10th, 1907.

Most of you are doubtless aware of the teaching that patients should not be operated upon until they are "well under" but I venture to hope that the considerations which I have placed before you will help you to understand the reasons upon which this teaching is based. There is in every case a particular point or juncture at which the operation should be begun, and if, from hurry or other causes, the surgical stimuli be prematurely applied the respiratory disturbances thus initiated may assume dangerous proportions. I need not weary you with details of cases. It is sufficient to say that intercurrent asphyxial symptoms demanding the most active treatment may thus arise as the immediate result of some surgical procedures during partial anæsthesia. In the most marked case which has come under my own personal observation the secondary venous engorgement of the tongue and adjacent structures was so intense that it was impossible to re-establish the airway to the larynx; artificial respiration proved unsuccessful; laryngotomy became necessary, and the patient's life was only saved by direct lung inflation.

The preventive treatment of respiratory shock is self-evident. It is to secure deep anæsthesia before the operation is commenced. As to the immediate treatment the operation should be suspended, the lips and face briskly rubbed with a towel, the teeth separated, the fauces stimulated with the finger-tip, the tongue pulled forwards if necessary, and artificial respiration performed. Generally speaking this treatment will cause a rapid subsidence of the asphyxial phenomena and respiration will be resumed. Should it fail laryngotomy and direct lung inflation must be resorted to. The head should not be lowered, nor should the patient's body be inverted. Drugs must be studiously avoided.

CIRCULATORY SHOCK.

I find that I have careful notes of 71 cases in which circulatory surgical shock has occurred during general anæsthesia. This does not, of course, represent anything like the total number of cases in which I have met with this condition. During the first ten or 12 years of practice I employed ether much more frequently than chloroform in general surgical work, and as circulatory shock is comparatively rare under the former anæsthetic I naturally came across but few cases of this condition. But during the last ten years I have employed chloroform, usually after nitrous oxide and ether, in most surgical cases and have gradually become alive to the frequency of intercurrent circulatory changes referable to surgical stimuli. The result has been that whenever circumstances have permitted I have taken notes of the most marked of my surgical shock cases. The subject has, in fact, proved to be an exceedingly interesting one and well worthy of clinical study.

It is difficult to say whether certain subjects are more liable than others to the ordinary (circulatory) form of surgical shock during general anæsthesia. I am unable to discover any such predisposition in my records of the most marked cases which have come under my immediate notice. Of the 71 cases of circulatory shock of which I have notes 25 were males, 45 were females, and in one the sex is not stated. Their ages ranged from five to 75 years. These figures are, for obvious reasons, of little or no statistical value. Whilst one would naturally regard elderly patients and those who are at the time in a bad general condition as more likely than others to be affected, one has to remember that it is in these very subjects that one is usually able to work with that comparatively light anæsthesia which, as I shall point out to you, tends to ward off circulatory shock. In anæsthetising a young and vigorous patient one generally has to administer a comparatively large quantity of anæsthetic in order to abolish reflex movement and, if chloroform be in use, it is this deep anæsthesia which predisposes to circulatory shock. Patients with morbus cordis, who, as a general rule, tolerate a comparatively light anæsthesia very well, frequently surprise the surgeon by passing through a formidable operation without any marked pulse disturbance. In a few of my cases I have been informed that the patients have suffered with a "weak heart" or have been "liable to faint," and it is quite conceivable that there may be something more than mere coincidence in this fact. It may be that such patients are specially susceptible to circulatory shock, but so far as I am aware there is no direct evidence on this point, nor is there much evidence that elderly and feeble subjects, in whom circulatory shock takes place during an operation, are more prejudicially affected, so far as their recovery is concerned, than more vigorous patients. As to the anæsthetic or anæsthetics under which circulatory shock is most common there is no doubt whatever that chloroform is *par excellence* the agent which specially predisposes to this condition owing to its power of reducing blood pressure. It is clear that in the event of the surgical procedure producing temporary cardiac inhibition or vaso-motor depression, syncope will be far more likely to arise in a patient whose arterial tension is at the moment low than in one whose tension is at the moment high. Circulatory surgical shock is, indeed, comparatively rare under nitrous oxide and under ether, these anæsthetics causing little or no fall of blood pressure. Of my 71 cases chloroform was being used in 37, O.E. or A.C.E. in 22, and ether in 12, when the symptoms occurred. The next point is one of great interest and importance. It is that surgical shock is a phenomenon of *deep* anæsthesia, being a comparatively rare incident when the corneal reflex is present. This, again, is readily intelligible, for all physiological blood pressure tracings show a *progressive* fall of pressure as chloroform anæsthesia deepens and it is when this anæsthesia is fully established that the patient becomes specially susceptible to the ordinary form of surgical shock. If the operation be of such a nature that the anæsthetist can keep up a moderate anæsthesia—i.e., a state in which the corneal reflex is present—he will be able, as a general rule, to

S. R. Christophers, I.M.S., illustrating the Developmental Cycle of Piroplasma canis in the Tick: (1) the parasite enlarged in the gut of the tick and became a motile club-shaped body, which then left the gut and penetrated an ovum, becoming in the substance of this a "zygote"; (2) this zygote increased in size and broke up into "sporoblasts" which were found disseminated in the tissues of the larva; (3) these sporoblasts further divided and accumulated as "sporozoits" in the salivary glands of the nymph; and (4) also sporozoits accumulated in the salivary glands of the adult tick. Experiment showed that the adult took infection and the nymph and "daughter" adult gave infection and corresponding to this "sporozoits" were found in the salivary glands of the tick at both these stages. The cycle of development appeared thus to be a very simple and uncomplicated one. The next exhibit was one of the parasite, discovered by Darling in Panama, Histoplasma capsulata (1906). The parasite was an intracellular one resembling somewhat Leishman-Donovan bodies and existed in immense numbers in the lungs, the liver, and the spleen. The following new helminths were also exhibited: (1) a new Bothriocephalid in man from Tasmania or Syria; (2) a new Nematode in man from China; and (3) a new Echinorhynchus in man from British Honduras.

Dr. A. BREINL of the Runcorn Laboratory (Liverpool School of Tropical Medicine) demonstrated the Life Cycle of the Parasite of Sleeping Sickness. In rats with Trypanosoma Gambiense the disease ran a fluctuating course. While the parasites were increasing in the blood amitotic division of nuclei and longitudinal fission were observed, but no nuclear changes or marked dimorphism. When parasites were most numerous from 5 per cent. to 20 per cent. of trypanosomes were seen with a thick stainable band growing out from the micro-nucleus and extending towards, sometimes passing beyond, the nucleus. In some cases the band entered into direct contact with the nucleus, sometimes it passed round the side of the body; subsequently it disappeared. When the number of parasites was falling rapidly, trypanosomes were observed with a clear space round the nucleus in the lungs, the spleen, and the bone marrow. In the bone marrow and spleen there were also forms in which the trypanosome body had disintegrated with flagellum and remains of micro-nucleus detached. The nucleus was intact. These forms underwent further change. The nucleus of each parasite budded off a small micro-nuclear granule, from which a new flagellum grew out. The life cycle began again with these small trypanosomes. The micro-nucleus originated from the macro-nucleus. In subsequent division the process was analogous to separation of two kinds of nuclei destined to conjugate. There was a pair of such nuclei in each trypanosome, which united when the number of parasites was at a maximum. In rats infected with Trypanosoma Gambiense and treated with atoxyl some parasites became rounded, formed a distinct membrane, threw off the flagellum, and remained unchanged for a prolonged period. The method employed was that whereby blood films or "organ-smears" were fixed wet; they were then stained and mounted in the usual way. The specimens were fixed in Flemming's fluid.

Dr. A. NIERENSTEIN, also of the Runcorn Laboratory of the Liverpool School of Tropical Medicine, read a paper on the Treatment of Trypanosomiasis, which is printed at p.228 of our present issue.

Dr. J. L. TODD, of the same laboratory, described certain Parasitic Protozoa observed in Africa, dealing more especially with Leucocytozoon Ziemanni and with an interesting cycle of development of Trypanosoma loricatum of frogs.

The PRESIDENT observed that atoxyl now gave them some hope of encouragement in the treatment of trypanosomiasis. Arsenic undoubtedly had the power of deferring and postponing the fatal ending and it was reasonable to suppose that the chance of recovery was thereby increased. His plan was to give small doses of atoxyl and gradually to increase them, not going beyond 50 to 60 minims of a 10 per cent. solution. He considered that the suggestion to combine the atoxyl treatment with mercury was sound.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—An Art and Loan Exhibition will take place at the Doré Gallery, New Bond-street, London, W., from Nov. 1st to 21st next in aid of the funds of the Royal Waterloo Hospital for Children and Women.

Reviews and Notices of Books.

Ulceration of the Cornea. By ANGUS MACNAB, B.A., B.Sc. N.Z., M.B., Ch.B. Edin., F.R.C S. Eng., Chief Clinical Assistant, Royal London Ophthalmic Hospital. London: Baillière, Tindall, and Cox. 1907. Pp. 196. Price 5*s* net.

AN attempt has been made in this book to classify ulcers of the cornea upon a bacteriological basis. Doubtless this is a step in the right direction, though in the present state of knowledge the result is somewhat disappointing. Indeed, it is probable that it can never be wholly satisfactory, for though in many cases the infecting organism may determine the type of ulcer there are often other factors which play a preponderant rôle, notably the conditions of resistance of the tissues, profoundly modified as these are by general asthenia, endogenous toxins, "trophic" nervous influence, and so on. The aim of classification should therefore be rather towards a broad pathogenic basis than the narrower bacteriogenic.

Mr. MacNab has clearly devoted much attention to the bacteriology of corneal ulceration and this part of the work is by far the best and merits commendation. It is pervaded with the teaching of Axenfeld, the *doyen* of ophthalmic bacteriology, to whom the author dedicates the book, and owes much to the recent researches of German investigators, among whom Zur Nedden and Römer may be specially mentioned. An excellent chapter is devoted to the ulcus serpens, or, as the author prefers to call it, the pneumococcal ulcer. The clinical features, pathological anatomy, bacteriology, and treatment of ordinary hypopyon ulcer are very lucidly described and stress is rightly laid upon the importance of radical treatment of the lacrymal complications which are so often present in these cases and play so fundamental a part in their causation. Atypical hypopyon keratitis next receives attention and this chapter contains many facts relating to the bacteriology of the subject which will probably be new to many English readers. Streptococcus pyogenes, bacillus pyocyaneus, Friedländer's pneumobacillus, and aspergillus fumigatus are accepted as causal agents, whilst the association of bacterium coli commune, staphylococcus pyogenes, rosa hefa, hay bacillus, and others is more likely to be fortuitous. Bacillary ulceration includes diplobacillary infection with the organism first simultaneously described by Morax and Axenfeld, and marginal ulceration by Zur Nedden's bacillus which nearly resembles Friedländer's pneumobacillus. Mr. MacNab differs from previous observers in attributing ulceration of the cornea much more frequently to the bacillus duplex. When the frequency of diplobacillary conjunctivitis is taken into consideration it is by no means surprising that the organism should be often found on so-called "catarrhal" ulcers, but this is very feeble proof of an etiological relationship, though it seems to be the only one which the author brings forward.

Ulceration of the cornea occurring in acute conjunctivitis receives rather scanty discussion, particularly noticeable in gonorrhœal conjunctivitis which is quite inadequately treated. Even more pronounced is the falling off in the description of cornea conditions in which bacteriogenesis is obscure or out of court. These sections of the book seem to have been included merely for the sake of completeness, and as to the section on neuroparalytic keratitis few neurologists would accept the view propounded of the origin and distribution of the "trophic" nerves.

It is obvious that so large a subject as ulceration of the cornea cannot be exhaustively discussed in a brochure of 187 pages of text. Some parts are very elementary; others presuppose an advanced knowledge of the subject, as, for example, in the references to so-called ring abscess. It is in circulatory shock there is, as a rule, no muscular spasm, stertor, or stridor, and the colour is pale rather than cyanotic. It must be remembered, of course, that cases occasionally occur in which both varieties of shock co-exist as above mentioned. Circulatory shock is frequently mistaken for (2) simple chloroform over-dosage or toxæmia; and it must be confessed that in many cases it is difficult, if not impossible, to distinguish the two conditions. I have already stated that circulatory surgical shock does not, as a rule, occur when the corneal reflex is present. If it occurred during light anæsthesia we should not, of course, have any difficulty in diagnosing it from simple chloroform syncope. But as deep chloroform anæsthesia specially predisposes to circulatory shock it will be obvious to you that when chloroform is being pushed to full narcosis and when during the process sudden syncope arises it is often very difficult to say whether this syncope is or is not purely toxic. *In going through the notes of many hundreds of administrations I find that in nearly every case in which sudden symptoms have occurred under chloroform* these symptoms have arisen during some operation liable to produce shock. It is only within recent years that I have been forced, by the chain of clinical evidence, to place this interpretation upon the cases to which I am now referring. I believe, indeed, that the surgical procedure is far more *freqently the direct* cause of pallor and pulselessness under chloroform than is generally supposed—in other words, that the mistake is frequently made of ascribing to the anæsthetic symptoms which are only partly dependent upon its action. That the anæsthetic cannot be altogether absolved is proved by the fact that acute circulatory shock as, for example, from intestinal traction, does not occur during *moderate* chloroform anæsthesia—i.e., when the corneal reflex is distinctly present. The blood pressure must, in fact, be already reduced for the typical phenomena to arise. One of the great pioneers in abdominal surgery was in the habit of operating under what we should now term moderate anæsthesia. Reflex movement of the legs, reflex abdominal rigidity, occasional "straining," &c., very frequently occurred, but it was found that provided the breathing were satisfactorily performed the *circulation was well maintained.* Unfortunately, this moderate anæsthesia is impracticable in the abdominal surgery of to-day and it hence happens that *the door is* opened to circulatory shock by the deeper anæsthesia which is required. Circulatory shock in its typical form may *generally* be distinguished from pure chloroform over-dosage or toxæmia by its suddenness, by its occurring at the moment of some *particular nerve injury*, and by the rapidity with which *the patient* passes from deep to light anæsthesia when the anæsthetic is withheld and remedial measures are applied. Cases constantly occur in practice in which the true surgical character of some circulatory disturbance under chloroform becomes conclusively proved as the administration proceeds, the symptoms vanishing as the nerve *injury* subsides, although the depth of anæsthesia remains the same. Moreover, it sometimes happens *that a particular* surgical procedure capable of producing circulatory shock is repeated after an interval, during which the surgeon is engaged in a stage of the operation not *involving* shock, and the anæsthetist may distinctly recognise two periods of pulse depression, more or less acute, coincident with the *two procedures* in question. Thus the introduction of a large sponge into the abdominal cavity prior to some operation upon the stomach or bowel is very liable during *deep* chloroform anæsthesia to produce pallor, pulse depression, and coldness of the forehead. When the sponge is *in situ* and the surgeon is engaged in introducing sutures (the patient still being deeply under chloroform) the symptoms of shock *disappear.* Subsequently, however, when the sponge is removed (the patient still being deeply under chloroform but with a good pulse and colour and a warm forehead) the symptoms of shock recur. It is not a difficult matter, as a rule, to diagnose pure circulatory shock from (3) circulatory depression due wholly to hæmorrhage, the circumstances in which the pallor and pulse *depression* arise being sufficiently indicative. Sometimes, however, when a considerable quantity of blood has been lost and the surgeon is disturbing important parts, the symptoms of the patient may be due partly to one cause and partly to the other. As a general rule circulatory shock occurs comparatively early in *operations* and is characterised by slowness of pulse, whilst circulatory depression from hæmorrhage is generally met with in the later stages and is characterised by rapidity of pulse. Circulatory shock must also be differentiated from (4) intercurrent asphyxia due to such causes as the *latero-prone or prone* posture, the presence of mucus or blood within the larynx or trachea, &c. In all of these there is, as in *respiratory* surgical shock, an initial stage of respiratory embarrassment attended by lividity or even cyanosis, and the circulatory depression is a secondary phenomenon. At the same time it is not always an easy matter to say, in any given case, to what extent circulatory depression is *due to* circulatory shock, to respiratory embarrassment, or to hæmorrhage. I have known this difficulty in diagnosis to arise in a case of laminectomy; but as the pulse almost at once returned when the patient was moved from the prone into the lateral position it became clear, at all events in that particular case, that the circulatory depression was largely of respiratory origin. Lastly, sudden circulatory shock may be simulated by (5) the entry of air into a vein, but when the latter event produces acute symptoms the characteristic sound is generally to be heard.

The preventive treatment of circulatory shock rests partly with the surgeon and partly with the anæsthetist. With the measures generally adopted by the former we are hardly concerned on the present occasion. They are specially likely to be beneficial in feeble subjects about to undergo formidable operations. Amongst these measures may be mentioned the envelopment of all parts of the body except the part about to be operated upon in flannel or cotton wool, the *maintenance* of a room temperature of from 65° to 70°, and the administration of an enema of beef-tea and brandy just before the anæsthetic is given. Some surgeons have great faith in a preliminary injection of strychnine, but the beneficial effects of this drug are questionable. The preliminary injection of morphine ($\frac{1}{4}$ grain to $\frac{1}{6}$ grain), with or without atropine ($\frac{1}{100}$ grain), is certainly advantageous in carefully selected cases. *We probably* have in atropine a drug which should be more extensively used than it is at present, but further experience with it is needed before we can speak positively as to its value. Amongst the preventive measures which are in the hands of the anæsthetist I have already directed your attention to the most important—namely, the selection when possible of ether or of a mixture containing ether. Should chloroform be the selected anæsthetic an *attempt should be made to retain* a trace of corneal reflex when the procedure likely to induce shock is taking place. Should the operation be one which can be performed in the Trendelenburg posture and should chloroform be the chosen anæsthetic the adoption of this posture is certainly a most valuable preventive measure. The prevention of circulatory shock rests much more with the anæsthetist than is generally supposed. Should ether be contra-indicated on general grounds it *may perhaps be* administered temporarily during that particular part of the operation when the shock is likely to arise, or the C.E. mixture may be similarly used to replace chloroform.

The immediate treatment of incipient and moderate circulatory shock is as simple as it is successful. It is to suspend the anæsthetic and to allow the corneal reflex to return to a slight degree. By this procedure the pallor, the coldness of the face and *extremities, the slow* and *small* pulse, and the half-open eye may generally be quickly corrected, and fortunately this return to moderate anæsthesia *during circulatory* shock is not as a rule accompanied by inconvenient rigidity. A lessening in the depth of anæsthesia when circulatory shock begins to show itself should be looked upon as such an essential part of the duties of the anæsthetist that it should never be omitted. It is probably not an exaggeration to say that a considerable percentage of the more formidable operations of surgery are *not completed* as the surgeon would have them completed owing to the presence of too deep an anæsthesia. The erroneous dogma that to avoid shock patients must be profoundly anæsthetised still claims its victims and prevents the *successful issue* of many an operation. The rule should be, the greater the shock the lighter the anæsthesia; and with this rule to guide him the anæsthetist will *find that* he can frequently tide his patient over a critical period and so enable the surgeon to complete an operation which might otherwise have to be abandoned. Rubbing the face and lips with a dry towel is a valuable adjunct to the simple measure here described. Sometimes a lessening in depth of *anæsthesia* may with advantage be combined with a substitution of the C.E. mixture for chloroform or of ether for the C.E. mixture. Such a course is indicated in moderately severe cases. Sometimes, too, the patient's body cyclical albuminuria, pyrexia, and vomiting are described; then come the spasmodic affections, chorea, the *tics*, stammering, and other defects of speech. The disturbances of primary dentition are also considered at some length, but on the whole we think that this is one of the least satisfactory and convincing chapters. In the warmth of his argument in favour of the view that the symptoms incidental to the period of teething are not due to the physiological act of dentition but to some concomitant condition, the author takes a less philosophic and broad-minded view than in his handling of other subjects. May it not be that in the narrow jaw of the civilised child the physiological process of dentition becomes relatively pathological, just as in the case of the civilised woman the narrow and often rachitic pelvis makes the physiological act of parturition a distinctly painful operation? Moreover, we feel much inclined to challenge the statement that irritation of the dental branches of the fifth nerve can produce otalgia but not suppurative otitis media. Minor defects of this kind, if indeed they be defects at all, do not detract from the high standard of general excellence maintained throughout the work. All the chapters afford pleasant reading and most of them take the form of lectures which have been delivered before various societies but heretofore have not been published. The book has distinct literary merits apart from merits of a purely medical description; it *is* the work of a scholar and is full of fascination and suggestiveness, and moreover contains much cut and dried information. We commend it to the notice of all our medical brethren.

LIBRARY TABLE.

Surgical Diagnosis: A Manual for Students and Practitioners. By ALBERT A. BERG, M.D., Adjunct Attending Surgeon to the Mount Sinai Hospital, New York. Illustrated with 215 engravings and 21 plates. London: Henry Kimpton. 1906. Pp. 543 Price 16*s.* net.—It is true that diagnosis cannot be taught by books; in the wards and in the out-patient rooms the student must learn this most difficult part of surgery. The advances of the last 40 or 50 years have greatly enlarged the surgical field and new methods of diagnosis have sprung up. We have therefore more to diagnose than had our predecessors, but we have also more means of diagnosis, and books can give very definite assistance in utilising to the full these diagnostic aids. This book is as good as any that we have seen and it should prove useful if used in the right way. If used apart from a case it will not be of much value, but if the student employs it in connexion with actual cases it will do much to increase his powers of diagnosis. There are a few errors which should be put right in a second edition; for instance, on page 151 the title of an illustration is given as "parenchymatous stroma"; of course, this should be "struma," but in English struma is never used for a goitre and the text never mentions the word, so that we imagine that a reader might easily be confused.

Traveller's Practical Manual of Conversation in Four Languages: English, French, German, and Italian. London: E. Marlborough and Co. 1907. Pp. 144. Price 2*s.* 6*d.* net. —This will be a most useful little book for travellers on the continent to possess. In appearance it is just like a thin wallet or pocket diary and this inconspicuousness will be appreciated by many of those to whom frequent reference to such a book in public places is absolutely necessary. The book consists of Travel Notes, Conversations arranged in alphabetical sections commencing with "Apartments," "Arrival," "Bathing," "Breakfast," and so on, a section of numerals, and, lastly, a dictionary of useful words. We have noticed but few mistakes and those are accidental misprints. It may be as well to mention them so that they may be afterwards corrected. On p. 85 "gebleiben for "geblieben." On p. 86 "aupara-paravant" instead of "auparavant." On p. 111 "Gehion" for "Gehirn." On p. 116 "lirraison" and "dittribution" for "livraison" and "distribution." Although we certainly learnt at school that "jus" was French for gravy we apparently must ask on the continent for "sauce," although that word also is given as the equivalent of the English word "sauce." The book reminds us, and usefully so at this time of the year, that "J'aimerais piquer une tête dans la rivière" does not mean, as it appears to, "I should like to prick a head in the river," but means "I should enjoy a dip in the river." By the way, *apropos* of sauce and dipping, we think the French also have another funny way of saying "Take a dip" (no doubt it is rightly excluded from the book) by "J'aimerais me saucer," literally "I should like to sauce myself," although "saucer" is equivalent to the English souse or souce. The little book is certainly worth possessing.

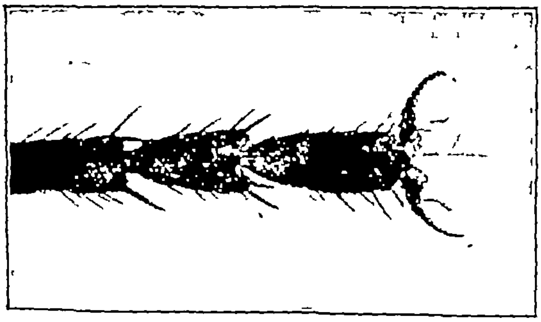
Text-book of Anatomy for Nurses. By ELIZABETH R. BUNDY, M.D., late Adjunct Professor of Anatomy and Demonstrator of Anatomy in the Woman's Medical College of Pennsylvania. With glossary and 191 illustrations. London: J. and A. Churchill. 1906. Pp. 252. Price 7*s.* 6*d.* net.—This book is written for the express purpose of giving the nurse who is working in the wards of a hospital a general idea of the anatomy of the human body. In preparing a work of this nature the difficulties which beset the writer are at once manifest. On the one hand, she must avoid the danger of bewildering her readers by setting forth a plethora of facts which can only be grasped by practical work in the dissecting-room, and, on the other hand, she must not treat the subject in too sketchy a manner. Dr. Elizabeth Bundy has struck the happy mean both in overcoming the inevitable difficulties of selection and in presenting the anatomical facts in a simple and intelligible manner. Generally the Basle nomenclature is adopted but in many instances the old names are bracketed with their successors. In arranging the contents the old plan of systematic anatomy is followed but the usual order of subjects is not strictly observed. For example, the description of the blood-vessels is deferred until the student shall have become familiar with the organs from which many of the vessels derive their names. The chapter on each system is prefaced by a short account of the histological anatomy of the structures described and, in addition, brief clinical and surgical notes, such as are suitable for nurses, are incorporated. This is a most important feature and we should like to have seen it developed to a greater extent. A recapitulatory chapter on important regions and structures, such as the triangles of the neck, the inguinal canal, the abdominal and thoracic viscera, and so on, brings the work to a successful conclusion. The illustrations, many of which are borrowed from "Morris's Anatomy," are very numerous and are well executed. The book should meet with a hearty welcome from all nurses, for without a proper knowledge of the human body many of their important duties become mechanical deeds instead of intelligent actions.

Atlas and Text book of Dentistry, including Diseases of the Mouth. By GUSTAV PREISWERK, M.D., Ph.D., of the University of Basle. Authorised translation from the German. Edited by GEORGE W. WARREN, A.M., *D.D S.* With 103 coloured figures on 44 plates and 152 text illustrations. London and Philadelphia: W. B. *Saunders* Company. 1906. Pp. 343. Price 15*s.* net.—The German edition of this handbook was noticed in THE LANCET of Jan. 30th, 1904. The translator, Mr. G. W. Warren, has carried out his task in a commendable manner and has so placed this useful work within the reach of English readers. The feature of the book is undoubtedly the excellent lithographic plates, especially those illustrating the ious

Typhoid Fever.

Experiment I.—Six house-flies were caught by means of a net in three enteric wards of the Glasgow fever hospital (September, 1903) and placed in Petri capsules containing a layer of bile salt, lactose agar, with neutral-red and crystal-violet—i.e., the medium of MacConkey[2] modified by Grünbaum and Hume.[3] This medium favours the growth of bacilli of the colon and typhoid groups, and inhibits most other species. For the sake of convenience and brevity this medium will hereinafter be designated L-R-V-B agar. The flies were allowed to walk over the surface of the medium for a short time and were then withdrawn. A few colonies of coliform organisms appeared on three of the nutrient surfaces but no trace of bacillus typhosus was found. It will be observed that a possible fallacy entered into this experiment inasmuch as the flies were caught in a fly net, the fabric of which would tend to remove any infective material clinging to their feet.

FIG. 1.



Part of a fly's foot showing the claws and pulvilli of the terminal segment and the general armature of bristles and spines. The clothing of short hairs is not visible in the illustration. × 70.

Experiment II.—To obviate the possible fallacy mentioned in the previous experiment seven flies were caught by means of sterilised forceps in the enteric wards of the fever hospital and each fly was immediately placed in a Petri capsule containing L-R-V-B agar over which it was allowed to walk for at least five minutes. No growths resulted in any of the capsules.

Experiment III.—It was therefore decided to make the test in a more direct manner by bringing flies (collected in the kitchen of a restaurant) into direct contact with the dejecta of typhoid patients—one patient being in the eighth day of illness, two in the eighteenth, and one in the twenty-fifth. This object was attained by placing each fly in a Petri capsule, having in the bottom half a thin film made from a typhoid stool by means of a sterilised swab. The fly was introduced within the Petri capsule before the film had time to become dry, and after walking over the surface for a few minutes it was transferred to the culture medium and allowed similarly to traverse its surface for a few minutes. Thereafter the fly was transferred to a second and in most instances to a third capsule holding a similar layer of L-R-V-B agar or ordinary agar. Many bacteria were deposited on the nutrient surface from the insect's feet in each case and they were numerous in some instances, even on the third surface. From two of the fæcal films the flies were found to have carried typhoid bacilli to the surface of the nutrient medium, but the number of these bacilli was relatively very small. Thus in the case of B—— (eighteenth day of illness) there was only one colony of bacillus typhosus amongst 22 colonies of other species and in the case of L—— (twenty-fifth day of illness) two colonies of bacillus typhosus amongst 60 of other species. No typhoid bacilli appeared on the second and third surfaces traversed by the flies.

Swine Fever.

Experiment IV.—An opportunity offered itself in an outbreak of swine fever in September, 1905, to test flies alighting upon pigs which had died from the disease and which had been subjected to post-mortem examination. The flies (*Musca vomitoria*) were caught by placing over them when quite still a wide tube of about one inch diameter (a Buchner tube). They at once rose into the inverted tube and were secured by a pledget of cotton wool which was pressed into the tube sufficiently to fix the insects so that they were prevented from moving about and removing any matter from their feet. In this way nine flies were collected from two carcasses and transferred to the laboratory. Each fly was placed in a Petri capsule containing a layer of ordinary agar and allowed to traverse the surface of the medium for about a minute. A very rich bacterial flora appeared on incubation, so much so that the agar was covered by a mixed confluent growth in most of the capsules. The bacillus of swine fever was isolated from one of the capsules. The flies were swarming on these carcasses and on other infective material, and were frequently seen to pass directly therefrom to the feeding troughs.

Staphylococcal Abscess.

Experiment V. (November, 1905).—Pus from an abscess containing staphylococcus aureus was spread in a thin film in the lower half of a Petri capsule by means of a sterilised swab. A house-fly was caused to walk over this slightly moist purulent film and was then transferred to another Petri capsule containing a layer of agar. After incubation at 37° C. for 48 hours the agar showed a profuse mixed growth in which staphylococcus aureus predominated.

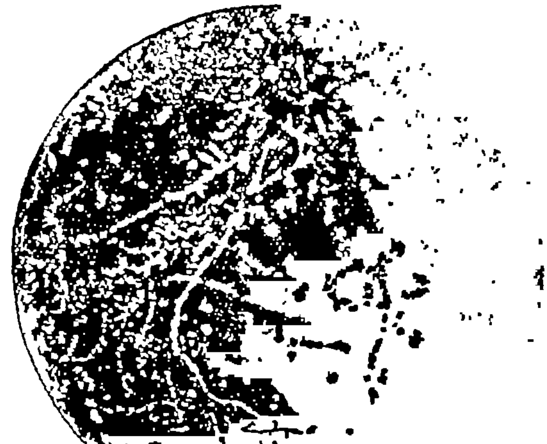
Pulmonary Tuberculosis.

Experiment VI. (November, 1905).—To test the carrying power of flies in the same way in relation to expectoration a specimen of tuberculous sputum rich in bacillus tuberculosis was spread in a thin film in the bottom half of a Petri capsule. A house-fly was introduced into this capsule and caused to walk over the film for a few minutes. It was then transferred to another Petri capsule containing a layer of agar. On washing the surface of the agar with one cubic centimetre of bouillon and inoculating a guinea-pig intraperitoneally therewith, tuberculosis was induced which killed the guinea pig in 36 days.

Anthrax.

Experiment VII.—In the course of the examination of a guinea pig dead from anthrax (October, 1903) it was observed that a blue fly had gained entrance to the laboratory and it was forthwith decided to make the intruder serve the purpose of an experiment. The fly was accordingly placed under a bell-jar. The carcass of the guinea pig, deprived of the skin and internal organs, was then placed under the same bell-jar. After alighting upon the moist surface of the carcass several times, the fly was transferred to a surface of

FIG. 2.



Growth of bacillus anthracis (24 hours) resulting from inoculation of agar surface in a Petri capsule by a blue fly which had just previously alighted on, and walked over, the skinned carcass of a guinea pig dead from anthrax (Oct. 28th, 1903).

strongly malty. This stout is known as "extra," which means that it is brewed from a strong wort, the proportion of malt used being greater than is usually the case. The stout was in good condition and free from acid flavour and an objectionable excess of carbonic acid gas.

(1) TABLOID BRAND COMPRESSED STERILISED DRESSINGS; AND (2) TABLOID SLIPPERY ELM WITH AND WITHOUT CARBOLIC ACID.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

1. We have already referred to the tabloid compressed ordinary dressings which are now issued after having been sterilised and thus afford the busy practitioner a ready aseptic dressing. They occupy very little space and are extremely compact. Amongst those recently received were: compressed absorbent gauze, double cyanide gauze, pleated compressed boric lint, pleated compressed triangular bandages, pleated compressed absorbent cotton-wool, and an open wove pleated compressed bandage. 2. The tabloid slippery elm represents five grains of the mucilage of slippery elm which is employed for its demulcent properties in the treatment of inflammatory affections of the respiratory, intestinal, and urinary tracts. Combined with phenol it may be used in throat affections and internally in diarrhœa and dysentery.

SOUTH AFRICAN WINES.

(J. SEDGWICK AND CO., CAPE TOWN. AGENTS, JEREMIAH LYON AND CO., 4, LOMBARD-COURT, LONDON, E.C.)

Year by year the quality of the wines produced in South Africa improves. As a rule they have shown in the past a somewhat high alcoholic strength and a relatively large proportion of sugar. The specimens recently sent to us by the above firm are, on the contrary, delicate in character, approaching in this respect the light wines produced in Western Europe. The red wine, for example, called Cabinet de Sauvignon, gave the following results on analysis: alcohol, by weight 10·85 per cent., by volume 13·43 per cent.; extractives, 1·57 per cent.; mineral matter, 0·21 per cent.; volatile acidity reckoned as acetic acid, 0·12 per cent.; fixed acidity reckoned as tartaric acid, 0·55 per cent.; and sugar, 0·80 per cent. Though not quite as delicate as a good claret this wine has a very acceptable flavour. It is clean and non-acid to the palate. It is somewhat "full-bodied" and is of the Burgundy type of red wine. The red Hermitage wine is decidedly light in character and the flavour recalls that of a good wine from the Medoc district. Analysis gave the following results: alcohol, by weight 9·71 per cent., by volume 12·05 per cent.; extractives, 1·30 per cent.; mineral matter, 0·25 per cent.; volatile acidity reckoned as acetic acid, 0·126 per cent.; fixed acidity reckoned as tartaric acid, 0·54 per cent.; and sugar, 0·78 per cent. This is a pure, sound, and pleasing type of red wine. Lastly, we examined a white wine known as Drachenstein which is a quite dry white wine of the Rheinwein type. It is, however, somewhat fuller in character than a light moselle or hock. Analysis gave the following results: alcohol, by weight 10·08 per cent., by volume 12·49 per cent.; extractives, 1·52 per cent.; mineral matter, 0·20 per cent.; volatile acidity reckoned as acetic acid, 0·09 per cent.; fixed acidity reckoned as tartaric acid, 0·607 per cent.; and sugar, 0·190 per cent. As will be seen, the wine is relatively free from sugar and is practically free also from volatile acidity. The figures are exactly what might be expected judging the merits of the wine from the point of view of flavour.

GERM PROOF FILTER.

(THE ATKINS FILTER ENGINEERING AND WATER SOFTENING CO., LIMITED, 71, SOUTHWARK BRIDGE ROAD, LONDON, S.E.)

This filter consists of a container in which three filter tubes of the Pasteur-Chamberland type are fixed. The filtering material is well known to be proof against the passage of organisms, the only drawback being the slow rate at which the water filters through. Extreme filtering efficiency can, however, only be secured by the very slow passage of the filtrate. We found that the rate of flow was about five fluid ounces in half an hour, 13 fluid ounces in one hour, 19 fluid ounces in two hours, and about 10 pints in 20 hours.

NOVIO TOILET PAPER.

(THE PAPER CUTTING AND TOILET REQUISITE CO., LIMITED, CHADWICK WORKS, 26, GROVE-PARK, CAMBERWELL, LONDON, S.E.)

We found that the statements made in regard to the merits of this paper are correct. The paper at any rate is free from injurious or irritating substances, is smooth, and while firm becomes soft and apparently soluble like thin rice-paper in contact with water.

SCOTCH WHISKY.

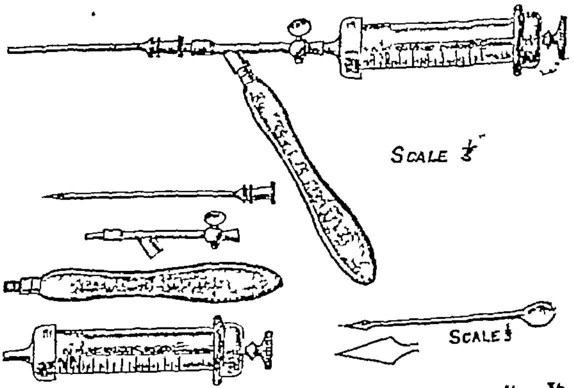
(JULIA HANSON AND SONS, LIMITED, TOWER STREET, DUDLEY.)

There can be no question that this whisky is not only an all-malt spirit but one also that has been thoroughly matured. It is somewhat full in flavour but is nevertheless smooth and soft to the palate. The claim that it is relatively free from acidity is correct, a claim which has induced the vendors to call the spirit an "anti-gout and rheumatic whisky." In cases in which a stimulant is advisable or allowed by the medical man of course the purest and oldest should be employed, but the use of the expression "anti-gout and rheumatic" in the title of the spirit is objectionable. Our analysis gave the following results: alcohol, by weight 41·80 per cent., by volume 49·29 per cent., equal to proof spirit 86·37 per cent.; the volatile acidity amounted to 0·02 per cent. reckoned as acetic acid. The secondary products amounted in all to 421·54 grammes per hectolitre of alcohol present. This whisky is particularly rich in ethers, the amount being 158 grammes per hectolitre of alcohol. From this standpoint this whisky should serve for the same medicinal purposes as genuine old brandy.

New Inventions.

SPINAL ANALGESIA APPARATUS.

THE accompanying illustration gives a good idea of a lumbar puncture apparatus which was made for me last year by Messrs. Allen and Hanburys, Limited, 48, Wigmore-street, London, W. I have had it in constant use since then for the induction of spinal analgesia with novocaine, and as it may interest my surgical confrères the following particulars will describe it. It consists of two needles, a needle-holder, syringe, and puncture knife. The needles, which measure three inches in length, are very fine ones (No. 17 and 18 gauge), composed of steel or platinum and iridium. I always use one of the latter, as it has the advantage over steel that it does not rust; but its disadvantages are that its edge is apt to get blunt more readily and the price is much more expensive. Their points are bevelled as near a right angle



A NEW MICROSCOPICAL DIAGNOSTIC METHOD AND SOME SIMPLE METHODS FOR STAINING LIQUID BLOOD.[1]

BY RONALD ROSS, F.R.S., C.B., F.R.C.S. ENG.,
PROFESSOR OF TROPICAL MEDICINE IN THE UNIVERSITY OF LIVERPOOL;
J. E. SALVIN-MOORE, A.R.C.S., F.L.S., F.Z.S.;
PROFESSOR OF CYTOLOGY AND DIRECTOR OF THE CANCER RESEARCH LABORATORIES;
AND
C. E. WALKER, F.L.S.,
ASSISTANT DIRECTOR OF THE CANCER RESEARCH LABORATORIES.

IN a recent publication[2] we discussed certain strings of granules which can be found by means of appropriate staining in a percentage of the red corpuscles in health and disease. We showed that they are the remains of the nucleus of the original cell and called them *chromolinin granulations*. In health they occur roughly in about 1 per cent. of the corpuscles, but in a few pathological conditions which we studied they occurred much more frequently. Thus, in a case of tropical abscess of the liver they were found in 6·6 per cent. of the corpuscles, in a case of chronic malarial anæmia in 11·5 per cent., while in ankylostomiasis, kala-azar, and rats with trypanosomes and spirochætæ they were detected very frequently. We inferred that an excessive percentage of corpuscles with the granulation was indicative of the discharge of the red corpuscles into the blood stream at an earlier stage in their development than usual, due probably to processes of blood destruction and regeneration which, so far as we know, cannot be estimated by other methods. We now write to call the attention of clinicians more pointedly to the phenomenon in the hope that a study of it in many diseases will prove useful for diagnosis and treatment.

Probably the simplest method for demonstrating the granulation is the glass-rod method of liquid staining described by one of us hereafter. A polychrome saturated solution of methylene blue in 0·5 per cent. salt solution should be used. In about a quarter or half of an hour many of the red corpuscles are found to contain minute blue points, often lying in strings, either few in number or so numerous as to fill a large part of the corpuscle. The granules look like small particles of stain adhering to the surface of the corpuscle; but, of course, are not really of this nature. True nucleated red corpuscles can be easily distinguished by the fact that the nuclear membrane is still intact.

To estimate the percentage of granular red corpuscles as quickly as possible the following procedure is the best. The whole area of the field should not be examined, but the corpuscles should be passed rapidly in review one by one across the centre of the field and be counted as they pass, and as each granular corpuscle comes up an assistant should score a mark on a piece of paper. In this way nearly a hundred corpuscles may be scrutinised by the minute. In order to avoid serious error of "random sampling" at least a thousand corpuscles should be examined; but if the percentage of granular corpuscles is over 5 of this first thousand corpuscles we should examine another thousand, or if it is over 10, 15, &c., we should examine another two or three thousand, &c.

Many of the granular corpuscles, when stained with polychrome methylene blue, will often be found to contain after half an hour, in addition to the blue granules, one or more large deep crimson dots. These are the centrosomes of the original cell, as shown in our paper already referred to. It is possible that an estimate of the percentage of granular corpuscles which contain them will also prove to be of assistance in diagnosis. Nissle has independently just called attention to what appear to be the same bodies but does not give drawings.[3]

Some Simple Methods for Staining Liquid Blood, by Professor RONALD ROSS.—The staining of dried films is now being abandoned more and more for cytological work, and it may therefore be worth while to describe briefly some methods for making sufficiently thin stained films of liquid blood. Several such are given in text-books of hæmatology. One of the oldest, which was suggested by Soulié in 1890,[4] but was probably known long previously and has certainly been often re-discovered since, consists in spreading and drying a film of alcoholic solution of a stain on a glass slide and then placing over it the cover-glass charged with a droplet of blood. The elements soon take up the colour and beautiful preparations can be made, though there is often much granular matter and the blood does not always spread well.

1. *Glass-rod method.*—The plan of mixing the droplet of blood with aqueous solutions of stain in various ways has, of course, been largely used. The difficulty lies in getting a sufficiently thin film, because as a rule there is too much fluid in the mixture to allow of a single layer of corpuscles being obtained. After trying many methods I find the following one to be the simplest and best. A large drop of blood is taken up on a glass slide, and a drop of stain, not larger than the drop of blood, is quickly placed close beside it with the end of a glass rod. Then, with the other end of the rod the two drops are thoroughly mixed together, and small quantities of the mixture (say, of the size of a pin's head) are transplanted on to several other slides (just previously wiped clean from dust), where each is covered with a cover-slip gently let down upon it. The smaller the droplet of mixture transplanted the thinner the resulting film, and the advantage of the use of the glass rod in this manner is that we can transplant droplets as small as we please and consequently obtain films of any tenuity we may wish for. Specimens for a considerable class may thus be made from a single drop of blood. Aqueous solutions of many stains may be employed and will not generally dissolve the red corpuscles if the amount of solution used is not in excess of the amount of blood.

One of the most useful stains is an old polychrome filtered saturated aqueous solution of methylene blue in 0·5 per cent. salt solution. Large areas, with separate corpuscles in single layer, yet not too much crushed, are obtained, just as in the best dried films. The leucocytes and blood plates are stained almost at once, although the background is almost colourless. A little later the red corpuscles take a blue tinge, and the chromolinin granules and centrosomes of a certain percentage of them[5] (which are not easily disclosed in dry stained films) begin to show up—the granules coloured blue and the centrosomes deep ruby red. The centrosomes of leucocytes are also coloured red; and it is important to note that the blood plates show similar minute red points, which, if they also are centrosomes, as is possible, will establish the long-contested cellular nature of these bodies. Trypanosomes can be well stained by several reagents. I am beginning to use this method generally in place of the ordinary unstained wet films.

2. *Agar method.*—Ordinary nutrient agar is melted and mixed with filtered saturated solutions of various stains (e.g., polychrome methylene blue) and poured on sloped glass slides, so as to obtain very thin films of the stained agar on the glass. The agar sets on the glass almost at once but does not dry until some time later. While its surface is still moist a coverslip charged with a droplet of blood is dropped upon it. The blood spreads out beautifully, the red corpuscles being generally disposed in a single layer of perfect discs. In a few minutes the elements take up the stain by adsorption from the stained agar, centrosomes and chromolinin granulation becoming apparent later. The picture is similar to that of Method I. but perhaps a little inferior, as the staining is not so vivid and the background is not so clear. Deetjen, so far as he can be understood, seems to have used this method but only partially in his study of blood plates[6]; but on the whole I do not think it is as good, even for this purpose, as Method I. The agar should be as deeply stained as possible, so as to stain the cells quickly; but the film of it on the glass should be as thin as possible, so as to allow sufficient light through it.

3. *Drained drop method.*—Thin liquid films are usually obtained by pressure between two surfaces of glass, but the following method gives a very thin liquid layer on a single surface. A coverslip is charged with a fairly large droplet of blood slightly spread out upon it and is then inverted on a shallow cell made with vaseline on a glass slide. This gives

---

THE LANCET.

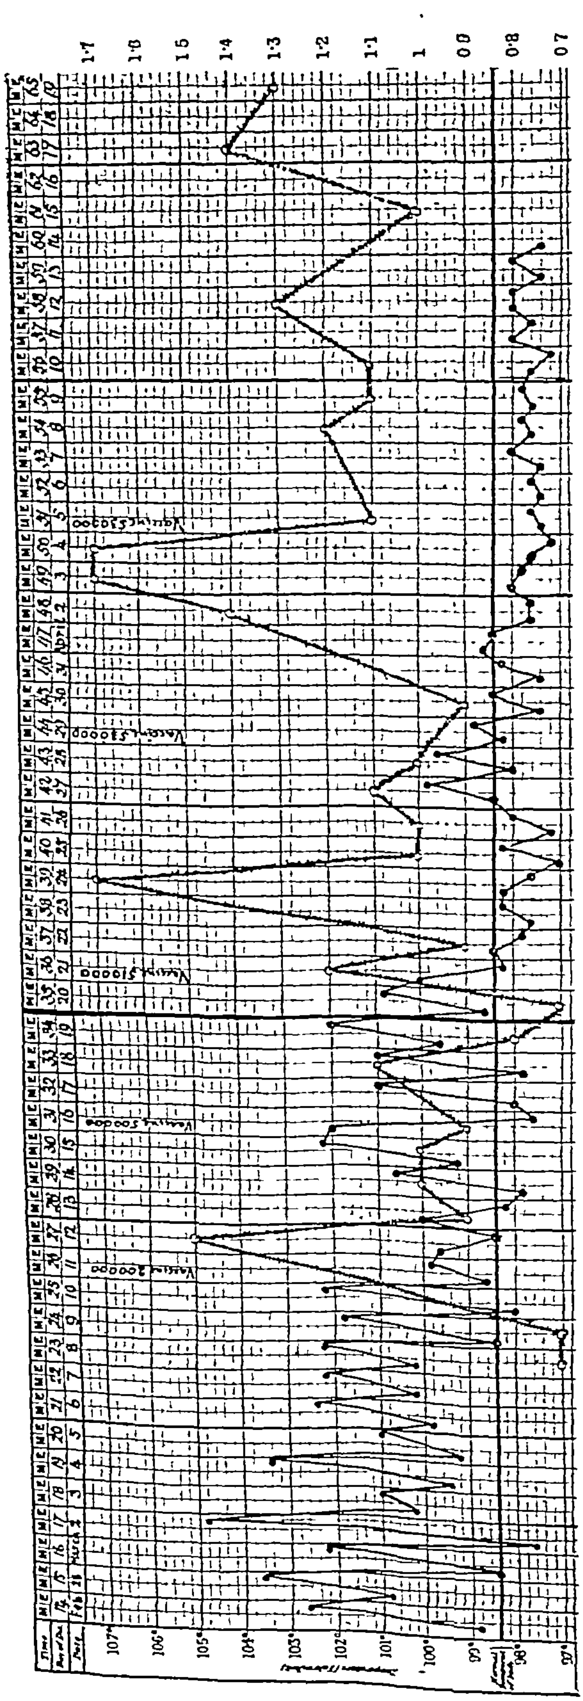
LONDON: SATURDAY, JULY 27, 1907.

The School in Relation to the Health of the Nation.

IT is no extravagant statement to assert that with the advent of the general medical inspection of school children and the teaching of the elementary laws of health to the older children a new dawn is breaking in the evolution of preventive medicine; indeed, hitherto the scope of preventive medicine, limited as it has been to a few only of the acutely infectious diseases, has been altogether too contracted. There are few diseases which are not preventable at least in some degree, more especially if they can be recognised early in their course. Of all preventable conditions which are likely to respond to well-directed educational efforts infantile mortality is by far the most important and most promising, inasmuch as its reduction is very largely a matter of education. There are, indeed, indications that it is only by the knowledge which will follow in the wake of medical inspection and the teaching of hygiene that any substantial reduction can be made in the volume of that great river of mortality which in certain areas of our large towns bears away some 200 of every 1000 children before the first anniversary of their birthday. The full harvest of such inspection and education will not be reaped for many years, not, indeed, until the health conscience which should become developed has resulted in a fitter and fuller motherhood than at present obtains and a knowledge of the factors which make for health and fitness has become appreciated and acted upon. At present we concern ourselves but little with future generations, and there is force in HERBERT SPENCER'S scathing criticism that if the earth were suddenly to become uninhabited and it could be visited a few years hence by people from another planet, Mars perchance, they would on examining our books conclude that, although we wrote on multitudinous subjects, we were clearly a sterile people, since nowhere was there to be found in our books for the young any indication that they were ever expected to become fathers or mothers. It is a strange commentary upon this satire on the part of the prince of philosophers that it is only when a stationary condition of our population is actually threatened by a steadily diminishing birth-rate and an excessive infantile mortality that we are awakening to the desirability of educating and improving the physique of future mothers and fathers. Already there are signs that the medical inspection which is taking place is resulting in a marked improvement in that first essential of health, the cleanliness of the children, and the defects which are being detected in the physical condition of the children hold out promise that many of such defects are preventable or at any rate amenable to great diminution.

The degree of progress which is likely to ensue in consequence of a general scheme of medical inspection and education depends in a paramount degree upon the medical profession as a whole. It is the general practitioner who must be responsible for the treatment of the defective condition of the children revealed by medical inspection. The systematic adoption of the inspection of school children means that there is to be a great searching out of diseased and defective conditions, many of which without such inspection might never be brought to light and consequently never treated. It means that in one capacity or another there will be much more work for medical men to do, and the amount of such work should increase *pari passu* with progress in our diagnostic methods, such, for instance, as is being made in the detection of the early signs of pulmonary tuberculosis. Already medical officers of health when opportunities have offered have organised inspections which have shown clearly what an enormous wastage of physical fitness is taking place and what a large number of children there are who start on the race of life with an unnecessary handicap by virtue of some removeable or remediable defects and who must soon succumb and become dependent upon relatives or the State for maintenance. We are likely to hear much of all this at the forthcoming Congress on School Hygiene which will meet in London early in the coming month, and it is to be hoped that out of that congress there will be crystallised some systematic scheme for dealing with the whole question of the medical inspection of school children and the teaching of elementary hygiene in a fashion easy of comprehension. It appears to us that in so far as local organisation is concerned the interests of economy and efficiency point to the medical officer of health. Several of the more important towns have now in operation a scheme of medical inspection under the administrative control of the medical officer of health, and in our view such control, at least in large urban districts, should be left or placed in his hands. As regards purely rural districts the matter is more complicated, any advantage there would be in intrusting the control to the county medical officer of health being counter balanced by the more intimate personal knowledge that would be possessed by the general practitioner. This is a difficult point which we commend to the deliberations of our readers.

The Inter-Departmental Committee on Medical Inspection of School Children thought that there were obvious advantages in the medical officer to the education authority being also medical officer of health. The duties of the two offices naturally overlap as, for example, in the inspection of school children with a view to prevent the spread of infectious disease, and in supervising the sanitary condition of the schools. Supervision in this sense cannot be removed from the medical officer of health who must also be in frequent communication with the teachers as regards suspicious illness amongst absentees, and who has, or should have, at his disposal means for bacteriological examination as well as for improving the home conditions of the children. The question of the treatment of defective and diseased children discovered by the medical examination is a difficult one. So far no treatment other than that occasionally



The dotted line represents the curve of the opsonic index. The figures on the right give its numerical value. The black lines represent the daily temperatures.

Preparation of vaccine.—A 24-hours old culture was inoculated into sterile normal saline solution and placed in a water bath at 60° C. for half an hour; nasgar tubes were inoculated from it and incubated overnight to test sterility. The number of cocci contained was estimated by mixing known volumes of washed normal blood and vaccine; these were then diluted with normal saline solution, films prepared at once and stained by Leishman's method. The number of organisms present was counted against the red blood corpuscles. The vaccine was freshly prepared for each of the first four doses; the fifth had been made seven days before use. No local reaction was observed after any of the injections.

Opsonic index.—Equal parts of leucocytes, emulsion (24-hours old culture in 0·1 per cent. NaCl), and serum were mixed together and incubated at 37° C. for ten minutes; we found that 15 minutes made the count extremely difficult to perform from excessive vacuolation and rapid degeneration of the cocci. The smears were stained by Leishman's method; at least 200 leucocytes were counted. The changes in the index and temperature are best seen by observation of the chart. The first inoculation (200,000) was made on March 11th, the index having been then 0·7 on two consecutive days; on the 12th it rose to 1·5 but fell again to 0·9 and 1 on the 13th, 14th, 15th, and 16th. As this dose had produced no harmful effects but had been followed by temporary alleviation we repeated it (500,000) on the 16th. A small rise in the index was observed on the 18th; on the 19th and 20th a fall was recorded, but on the 21st the index had risen to 1·2. A further dose (610,000) was given and a slight fall on the 22nd was followed by an abrupt rise on the 23rd. Within 48 hours the index had again dropped markedly. The events following the first inoculation had repeated themselves. As the index remained comparatively low on the 25th, 26th, 27th, and 28th, with a slight tendency to rise of temperature on the two last days, a fresh dose (530,000) was given on the 29th. The index fell slightly, followed by a rise which was well maintained until April 4th. On the 5th the index had dropped to 1·1. What proved to be the last inoculation was made on this day. A slight rise was noted on the 8th. The subsequent indices are recorded on alternate days. Since the inoculations were on each occasion followed by a rise in the index, and on three occasions by a rise of so marked a character, it seems reasonable to suppose that there is a connexion between the two events.

Agglutination.—These experiments were performed within five hours of the removal of the blood, by the platinum loop method, microscopic examination, laboratory temperature (12°–15° C.) except on one occasion mentioned in the text. The organisms were obtained from 24 hours old "nasgar" cultures emulsified in 0·1 per cent. salt solution. Controls were invariably negative. Five sets of experiments were performed.

A.—To test the agglutination of normal serum on the Liverpool coccus This was done on six occasions; once a 1 in 5 dilution agglutinated in ten minutes; subsequent experiments failed to repeat this. Higher dilutions were invariably negative; time, one hour.

B.—To test the agglutination of the Liverpool coccus by the patient's serum. The table given below shows that during the period of the observations the agglutination reaction was at a maximum from the fortieth to the fiftieth day of the disease, and from that date has shown a steady decline.

Day of disease.	Dilutions.		
	1 in 50	1 in 100.	1 in 500.
36	15 mins.	—	—
40	10 „	25 mins.	47 mins.
50	12 „	25 „	—

72	87 mins.	Neg. 105 „	—

Neg. = Negative.

C.—To test the agglutinating power on the Liverpool coccus of the sera of patients suffering from other diseases.

It is to be observed also that a copy of any certificate must on payment of the prescribed fee be given to an employer or a workman by the certifying surgeon, and for such a copy a fee of 1*s.* is to be paid. The regulations made under such Acts as the Workmen's Compensation Act and the Act itself, where they have to be read in combination with the Factory and Workshop Act, may seem a little complicated but will become comparatively clear to those for whose guidance they have been framed as soon as they have had occasion to apply them to a few actual cases.

Trypsin in the Treatment of Cancer.

THE number of remedies which have been brought forward for the cure of malignant disease is very great and the hopes of the public, and also of the medical profession, are raised from time to time by some new discovery or by the employment of some well-known drug; but experience has always shown that the much vaunted remedy cannot accomplish that for which it has been given and a feeling almost of hopelessness arises. We have so often been deceived by promises that have not been fulfilled that we cannot but view with a certain amount of doubt any new claim. This hesitation in accepting the claims of those who say that they have cured cancers by other than surgical treatment must be beneficial, for it leads to the thorough testing of new remedies. At the Middlesex Hospital it is a definite part of the work of the cancer department to test all new "remedies" for malignant disease and the tests are applied with absolute impartiality, no treatment being condemned as useless until it has been shown definitely to be of no value. In a daily newspaper recently the writer of an article on the use of trypsin in the treatment of cancer complains that "there have been a large number of imperfect trials which have resulted in failure and which have been seized upon by those who are constitutionally incapable of appreciating anything new and by those who have had even less creditable motives for their attitude." It is difficult to guess to whom the writer refers in the latter part of his paragraph, for everyone would welcome with open arms the advent of a genuine remedy for cancer, and none would welcome it more than members of the medical profession for they see more of the pain, the discomfort, and the misery resulting from malignant disease than does any other section of the populace. But medical men also know more of the failures of the remedies proposed for cancer; the apparent successes readily find their way into print, but the many certain failures are much less likely to be recorded.

How does it happen that credit has been given to many substances as remedies for malignant disease while subsequent trial has shown that they are useless? Whenever we find very many substances offered as remedies for the treatment of any morbid condition we may be sure that one or more of the following circumstances are present. The disease may have a natural tendency to abate, whether any treatment be adopted or not; when this is so, the last treatment employed is likely to have the credit of the improvement. Or there may be natural fluctuations in the rate of progress of the malady; any remedy that coincides with a temporary arrest of its progress will have ascribed to it that arrest, even though there may be no connexion between the two. And lastly, a fruitful source of undeserved reputations of drugs in the treatment of obstinate diseases is to be found in errors of diagnosis. In the history of the drug treatment of cancer we can find many instances of the last two of these fallacies. All who have had many opportunities of studying clinically malignant disease have recognised the wonderful variations which occur, and not merely in different cases, though that is very striking. In one patient a cancer of the breast may grow with great rapidity and a few months from the earliest sign may see the fatal result, and in another patient a growth of the breast, equally cancerous, may last some ten, 15, or even 20 years, and, in fact, the patient may die from some intercurrent malady and not from the malignant growth. These differences occur in different persons, but very similar variations may, and often do, occur in one and the same patient. At times a cancer may progress rapidly; in a few weeks or months a small nodule may attain huge dimensions and cause much pain and then without any obvious change in the circumstances, without any modification of diet, drugs, or mode of life, in fact, without any apparent cause, the rapidly growing mass may suddenly cease to enlarge; or it may shrink and all pain may be absent, and for a time this cessation of growth may last, and then after a longer or shorter interval the tumour may again take on active growth and rapidly lead to a fatal issue. Sometimes the slackening of the progress of the cancer may be permanent; years may pass by and but little change be observed. Nay, more, the halt in the increase of the malignant growth may be followed by very sensible diminution in the size of the tumour and this diminution may continue until what at one time was an enormous mass may have dwindled until only a small nodule remains and cases have even been recorded where a growth has absolutely disappeared. And in some of these cases there can be no question of a mistake in diagnosis, for there are cases of cancer of the breast in which surgical removal of the growth has been followed by recurrence; histological examination of the original mass has settled beyond question the malignant nature of the tumour and yet the recurrent nodules have disappeared completely. Should any of these ameliorations of the signs and symptoms of a cancer have coincided with the administration of Chian turpentine or extract of violet leaves or any other belauded remedy then it is only natural that the drug employed should be credited with the improvement that has occurred, and it cannot be doubted by any careful observer of cases of malignant disease that this explanation is true of the reputation that has been gained by many substances.

There is, however, an even more potent source of error in this matter, and that is faulty diagnosis. It sometimes happens that, even when a growth has been removed and has been examined by the naked eye and microscopically, it has not been possible to say with absolute certainty whether it is malignant or not, and if this be so when we can examine a tumour with all the resources at our command how is it possible always to guarantee the malignancy of a growth in the living body? It must be allowed by all who are conversant, clinically and histologically, with the subject that this liability to error in diagnosis is very great, and if it is great with those who

A STUDY OF THE CONDITIONS PRODUCING THE ANOMALOUS REACTION NOT INFREQUENTLY MET WITH ON TESTING URINE FOR SUGAR WITH FEHLING'S SOLUTION.

By F. W. PAVY, M.D.Lond., LL.D., F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL; HONORARY PHYSICIAN TO KING EDWARD VII. HOSPITAL.

It falls within common knowledge that on testing urine for sugar with Fehling's solution a reaction may be obtained which is so at variance with what is ordinarily met with as to give rise to no inconsiderable embarrassment. The anomalous reaction to which I am alluding has recently formed the subject of consideration in a communication on "The Detection of Sugar in Urine, &c.," by Dr. A. M. Kellas and Dr. F. J. Wethered to be found at pages 1058 and 1136 of the second volume of The Lancet for 1906, and in an article entitled "Observations on Fehling's Test for Dextrose in Urine," by Dr. Hugh MacLean published in the *Bio-Chemical Journal*, vol. i., p. 111, 1906. Through these communications I have been prompted to conduct the inquiry which has resulted in the information being obtained which I propose herein to set forth. In view of my long association with the operation of testing for sugar the undertaking has afforded congenial work. In addition, I may say that I have been impressed with the feeling, on looking at the value of Fehling's solution as a urinary test and the extensive employment it commands, that it might well be considered worthy of the bestowal of efforts to clear up an anomalous behaviour that is not infrequently observed to follow its application to certain kinds of urine.

The point to be determined is what stands at the foundation of the varieties of anomalous behaviour of the test that are observed. The essential action which in all circumstances takes place is a reduction of the cupric oxide to the state of suboxide. Under what may be spoken of as the normal reaction, or that occurring when the test liquid is boiled with *an aqueous solution of glucose, the* suboxide formed presents itself immediately to view as a dense vermillion-red precipitate, which more or less quickly settles out of the liquid. However small the quantity of sugar the precipitate falls in the form mentioned when extraneous matter is absent and a sufficient quantity of Fehling's solution is employed. In the case of urine, when large quantities of sugar are present, a precipitate is immediately produced, but the colour of it is different, being observed to range from yellow to brownish red. In the presence, on the other hand, of small quantities, a wide difference is noticeable in the character of the result *occurring*. At first no precipitate may be produced and none even may show itself till after somewhat prolonged boiling or it may be *none may appear till after* the test tube has stood in the rack for a little time. The precipitate in these circumstances possesses a yellow colour which it retains without passing into the *pronounced* red, as happens in the case of the application of the test to urine containing a large quantity of sugar. It *sometimes* happens that a change of colour occurs without any definite settlement of precipitate. With this change the liquid assumes an opalescent or milky character and may be found in this state *on the following* day, the colour being either yellow, yellowish green, or another shade of green, according to the preponderance of yellow from reduced oxide or of blue from the unreduced test solution.

To what are all *these* points of variation attributable? Chemists tell *us that, as with the* cupric oxide, the cuprous oxide presents itself in the hydrated and the non-hydrated form, the former being stated to be represented by the yellow and the latter by the red product. The shades of colour from yellow to red that may happen to be observed are assigned to transition from the hydrated into the dehydrated state. It may be said to be in harmony with what might be expected under the view specified that the process of boiling should promote the occurrence of dehydration, and it is noticeable that it tends to promote the passage *of* a yellow into a red precipitate. In the case, for example, of a cuprous salt it is open to observation that the bright yellow precipitate which falls on the careful addition of a caustic alkali passes on subjection to ebullition into a red or brownish-red; and the phenomenon is attributed by chemists to the occurrence of dehydration. I shall show later that the alteration of colour is associated with an altered physical state rendered evident by the microscope.

At variance with the ordinary reaction attended with the production of a more or less copious precipitate, a reaction, as mentioned, may present itself in which there is a change of colour to different shades of green or even to yellow without any actually visible precipitate at the time of applying the test and perhaps the contents of the test-tube may even be found to have retained their opalescent or milky state on being looked at on the following day. To this form of reaction, so widely differing in character from the ordinary effect of sugar, I will proceed to give attention with the view, on the one hand, of ascertaining its meaning and, on the other, of unravelling the conditions leading up to its production. It may be taken as obvious that some definite operative agency must exist and this ought to be susceptible of disclosure.

There are other reducing bodies besides sugar in the urine—uric acid and creatinine may be specially named; and the question has been raised by some as to whether the anomalous reaction under consideration may not be due to the mode of reduction effected by one or other of these. The authorities to whose communications I have referred express the opinion that creatinine, by virtue of its presence as such, constitutes the source of the modified result, Dr. MacLean (*loc. cit.*, p. 116) particularising and stating that, "with regard to its power of masking the presence of small amounts of sugar, it is probable that the cuprous hydrate or oxide is held in solution by kreatinin."

The subject before us may be said to be one that has received considerable attention, but at the same time it may be considered that it has not been as yet exhaustively dealt with. From the nature of its surroundings it stands on very fitting ground for subjection to chemical investigation, and I have found that invaluable aid is afforded by the microscope in helping to unravel the intricacies embodied in it. Let us see what is learnt by a joint appeal to these two modes of investigation. Some years ago I gave consideration to the matter and expressed the view I had been led to entertain upon it. I will not at this stage say anything about this view, but will defer speaking of it until after the evidence obtained from the further inquiry that has been conducted has been set forth, so that the information thus supplied may be brought into use in dealing with the elucidation of the problem.

I will, in the first place, show what is attainable with the employment simply of Fehling's solution and a solution of dextrose. The formula of Fehling's solution differs to some extent as given by different authorities. The liquid which I have been in the habit of employing from a very early period contains potash instead of soda, and the amount of alkali is somewhat larger than that given in other formulæ for the test. The modification has appeared to me to yield a more stable and reliable test and for this reason I have adhered to it from the beginning. For the observations, however, recounted in this communication I have throughout adopted, as most in harmony with what is generally employed, the formula given by Allen in his work on the "Chemistry of the Urine" (Churchill, 1895), p. 59.

Taking two cubic centimetres of Fehling's solution and boiling it, as is done in the ordinary mode of applying the test to urines, with an equal quantity of a 1 per cent. solution of dextrose, the effect observed is the production of a vermillion-red precipitate of cuprous oxide of a sufficiently dense nature to be not long in settling to the bottom of the tube. In the presence of a larger amount of dextrose—an amount that is more than sufficient for the reduction of the cupric oxide contained in the quantity of the test liquid employed—the colour soon changes to a dark brown or even a brownish black, a result (often noticeable in testing strongly saccharine urine) which is considered to be due to the action of the caustic alkali on the dextrose standing in excess.

If now, instead of taking equal quantities of the two solutions, the dextrose be diminished by adding five drops only of its solution to the two cubic centimetres of Fehling's solution, the character of the precipitate produced on boiling is found to remain unaltered, but of course *the amount of it* is less. With one drop, even, a like result is observed, and indeed, however small the amount of sugar added, whatever precipitate is formed when the method of procedure under consideration is followed, shows itself on settling in the form of the deep red cuprous oxide. Whilst have not sufficient data to be certain of the correctness of the diagnosis.

At the Middlesex Hospital trypsin has been tried; in the first two cases there was no improvement in the patients nor was the progress of the growth influenced by the injections; but it may be objected that in these cases the preparation of trypsin may not have been potent, so later a fresh supply of the drug was obtained and each ampoule of injection was tested for digestive power. The injections were used on nine cases; in three of these treatment was employed for little more than three weeks and therefore they may perhaps be put aside. In the remaining six cases the treatment lasted from 66 days to 118 days. Of the six, two succumbed, one was sinking fast at the time of the last note, and three were still living. In two of those still living at the time of the report the weight had decreased; in the third it was stationary. The evidence of improvement in the six cases was as follows: in one there was distinctly less pain, in one there was a diminution of the stenosis of the rectum, and in one the disease was stationary. The treatment did not prevent most of the patients from showing a progressive loss of weight and except in one case no local improvement occurred. We have no wish to condemn the trypsin treatment; we have heard of cases where improvement appeared to have resulted from the trypsin injections. We have heard also of cases where no benefit occurred. When the treatment has been tested systematically both on mice and men it seems to have failed completely, and it is only by a thorough trial that we can come to a correct conclusion as to its value. No one will rejoice more than we shall should the treatment eventually prove of value, but hitherto we have seen no certain evidence of that value.

Annotations.

"Ne quid nimis."

THE NEW COURT APPOINTMENTS.

THE King has been pleased to appoint Sir Richard Douglas Powell to be one of the physicians-in-ordinary to His Majesty in the room of Sir William Broadbent, deceased. Dr. Bertrand Dawson, physician to the London Hospital, has been appointed one of the physicians extraordinary. The King has also been pleased to appoint Sir Thomas McCall Anderson to be one of His Majesty's honorary physicians in Scotland in the room of Sir William Gairdner, deceased. In the notice of these Court appointments, as it appeared in the *Gazette* on Friday last, July 19th, the name of Sir Thomas Fraser, also one of His Majesty's honorary physicians in Scotland, was substituted for that of Sir William Gairdner, with the result that many questions were directed to us as to how and when and where the well-known professor of clinical medicine in the University of Edinburgh had met his death. We were happy to be able to assure inquirers that he was, in his own words, "very much alive."

THE DESTINY OF CASE-BOOKS.

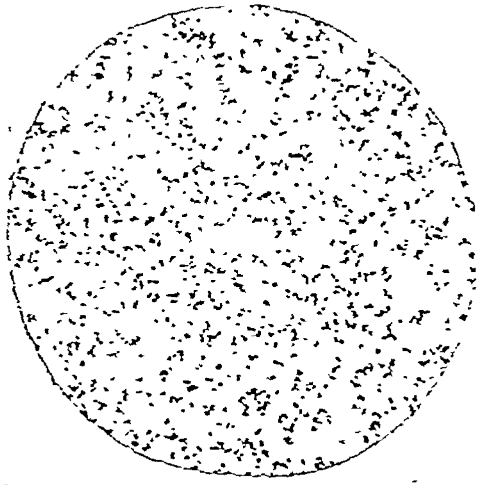
THE destiny of old case-books and notes of cases is one which concerns medical men and the public alike. What, as a rule, becomes of a medical man's written records of his patient's ailments? Generally speaking, these highly interesting and often compromising documents are handed on by each medical man to his successor in a practice, but where there is no such succession—what then? As a rule, when a learned man dies, unsympathetic legatees regard his books and papers with scant favour. Sometimes, on the part of a practical widow and her daughters, there occurs a great burning of "dear papa's old rubbish," but at other times there is a scattering to the four winds of heaven of documents that it would have been best to burn. This scattering is not necessarily rapid; it may last years and its final result may be that the most private memoranda have become matter of public comment by the literary pickers-up of unconsidered trifles. Medical men should, of course, make a point of leaving their case-books and other memoranda in safe hands, and this can be done either by will or on retirement from practice. Sir Astley Cooper's elaborate accounts of cases are now in a special or reserved collection in the library of the Royal College of Surgeons of England. This is as it should be. As the great surgeon always mentioned the names of patients and as those names are still mostly well known in England to-day, it is alarming to reflect what would have happened had his very circumstantial records of ancestral complaints fallen into the hands of nervous moderns to-day. But this might have, and has in other cases perhaps sometimes, happened.

THE PUBLIC TELEPHONE CALL OFFICE AS A FACTOR IN THE SPREAD OF DISEASE.

IT would be interesting to know the bacteriology of the air of public telephone call offices. The suggestion should stimulate the curiosity of the scientific staff of the London County Council, many of the inquiries of which have proved the insanitary conditions of many places in the light of bacteriological research. The public telephone call office appears to be singularly well designed for the capture and growth of pathogenic organisms. These little stations are usually carefully closed, are padded, and kept almost air tight; sunshine and fresh air seldom can reach the interior, while of course no attempt is made to keep them aired or ventilated, because any provision for securing ventilation is calculated to make difficult the hearing of the message. External sounds must be kept out, the box must be sealed against them, and when this plan succeeds it must succeed also in excluding with equal efficacy external purifying agencies. The telephone call station may be described, in fact, as a bacteriological box in which pathogenic and other organisms are carefully nursed. Infection of the imprisoned air must at all events be constantly taking place and this only too readily spreads whenever the opportunity arises. Caller after caller thus either may infect or receive infection so long as no steps are taken to purify the air within the station. It is a common experience of those who have occasion to use these call offices that unless the padded door which when closed is tight-fitting is left wide open (a plan which is not encouraged) the air within is frowsy, stale, and often has an offensive odour. Common sense appeals against this state of things and it would be safe to predict that the bacteriological examination of this air would tell an appalling story. Surely it would be simple enough to attach a system of ventilation to these call boxes which would not interfere with the articulation of the transmitting disc or prevent the message from being heard. The interior should be air-swept regularly or automatically and disinfected. We have heard of the septic condition of the receiver or tube into which the operator delivers his message and we know that it has been clearly demonstrated by scientific experiment that in the act of speaking *materies morbi* may be projected from the speaker's mouth for a considerable distance. With reasonable care such a risk of infection can be minimised, b olluted air of the cuprous oxide. *The solution constitutes a clear, colourless,* watery liquid. Owing to the solvent power mentioned when reduction of the cupric oxide contained in the cupric test solution is effected in the presence of ammonia, the result is the loss of the blue colour derivable from the cupric oxide, and the production of a perfectly colourless, watery liquid. Reduction is in no way interfered with, but the reduced oxide fails to make itself visible. The action occurring is turned to account for quantitative sugar determination in the application of the ammoniated cupric liquid which bears my name. If the ammonia be driven off by means of heat the cuprous oxide previously held in solution becomes precipitated, but, as the forthcoming evidence will show, it falls in a state somewhat modified from that presented under precipitation in the ordinary way.

To illustrate the effect of the presence of ammonia a 3 per 1000 strength of dextrose solution is a convenient one for employment. It is requisite that there should not be sufficient sugar to stand in excess of the cupric oxide to be reduced in the test solution employed. Two cubic centimetres of the 3 per 1000 dextrose solution do not fully reduce the cupric oxide in two cubic centimetres of Fehling's solution and therefore a certain amount of the test liquid remains unchanged. The precipitate produced on boiling the proportions named of the two liquids by themselves consists, as may be inferred, of the normal red cuprous oxide. This is seen to be dispersed through the liquid and afterwards to settle as a compact red deposit in the ordinary way. Examined microscopically it is found to present the usual nodular condition with the nodules cohering into irregular-shaped masses. If to a corresponding admixture of test and dextrose solutions five drops of strong solution of ammonia (specific gravity 0·880) be added, considerable boiling is required before any notable reaction is seen to occur. The first effect noticeable is that the intensity of the blue becomes somewhat diminished as a consequence of the reduction without precipitation that takes place. Then, as the ammonia is driven off, the contents of the tube may become suddenly opaque and in the first instance of a dirty green colour, which quickly runs into dirty yellow and afterwards brownish with a certain amount of reddish tint. The precipitate to the naked eye presents a very different appearance from that of the precipitate belonging to the normal reaction, *and microscopically it is seen to consist of conspicuously finer particles with seemingly a less strong cohesive tendency.* A representation of the character of the precipitate is given in Fig. 3.

FIG. 3.



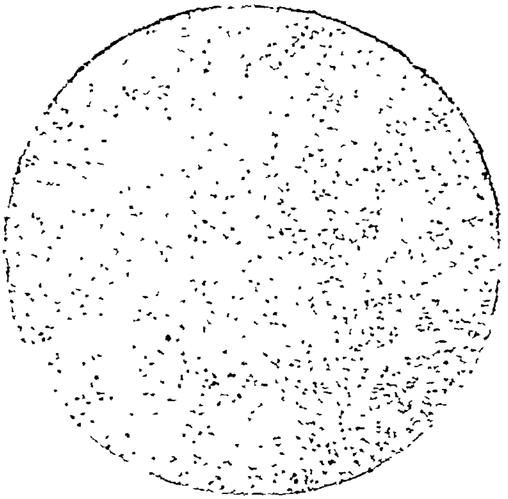
From photomicrograph of suboxide precipitate from two cubic centimetres of 3 per 1000 solution of dextrose, two cubic centimetres of Fehling's solution, and five drops of ammonia solution. Magnified 440 diameters.

Variations may be made in the strength of the sugar solution and the amount of ammonia with varying results as regards the colour of the product, and if enough sugar be present fully to reduce the cupric oxide of the test and enough ammonia to keep the suboxide formed in solution, the contents of the test-tube may be brought temporarily to a clear, colourless state, which with a further expulsion of ammonia suddenly changes and gives place to the presence of the suboxide in a precipitated form.

An instructive result is obtained by adding a little albumin to the admixture of Fehling's solution, sugar, and ammonia. Albumin has no reducing power in itself, and in small quantity (in large quantity it interferes with precipitation apparently through the extent of concurrent generation and evolution of ammonia occurring) exerts no influence on the character of the cuprous oxide precipitate produced. It is the normal red precipitate that falls in the presence of the albumin, just as happens without it, and microscopically the conditions in the two cases are practically alike. If, however, the ammonia and albumin are conjoined an effect is produced identical with what is noticed on applying the test to urine containing a slightly abnormal amount of sugar.

Taking two cubic centimetres of Fehling's solution, two cubic centimetres of a 1 per 1000 solution of dextrose, five drops of ammonia solution, and five drops of a 2 per cent. solution of dried egg albumin, and boiling in the usual way, the following is the result observed. Quite prolonged boiling is required before any change is perceived. Then the contents of the tube become milky and dark green, and, as boiling is carried on, the green passes into a lighter shade with a yellow tint. The condition agrees with what would be suggestive, if urine were being examined, of the presence of a slightly abnormal amount of sugar. By increasing the strength of the sugar solution to 2 per 1000 the reaction is of the same character, but more marked in degree. The microscopic appearance presented is totally different from that observed in ordinary circumstances and perfectly in accord with that belonging to urine exhibiting a similar kind of behaviour with Fehling's test. The field is studded over with exceedingly minute separated particles, so minute in the case of the 1 per 1000 strength of sugar solution as to require close attention to be given to see them. With a stronger solution they are more distinctly visible, but are still seen to be scattered in a more or less completely isolated state. The microscopic appearance fully accounts for the emulsion-like character belonging to the product. Fig. 4 gives a representation of the condition that has been described.

FIG. 4.



From photomicrograph of suboxide precipitate from two cubic centimetres of 2 per 1000 solution of dextrose, two cubic centimetres of Fehling's solution, five drops of ammonia solution, and five drops of a 2 per cent. solution of dried egg albumin. Magnified 440 diameters.

INFLUENCE OF URIC ACID.

I will now pass to the consideration of the part played by the cupric oxide reducing agents that are present in the urine in addition to sugar. The only agents of sufficient significance to call for attention are uric acid and creatinine. Let us see in what position these agents stand in relation to the matter that is under consideration, first dealing with uric acid.

Observation shows that uric acid behaves in a corresponding way to sugar in its reducing action upon Fehling's solution. The precipitate that falls consists of the red keeping of cats can be spread more widely by official action." The circulation of pamphlets in the vernacular is recommended, as "the native is by no means impervious to appeals of common sense." We quite agree with this but we are also of opinion that Major Julian's suggestion might well receive official encouragement.

THE BACTERIOLOGICAL EXAMINATION OF THE BLOOD IN TYPHOID FEVER.

IN recent years the value of bacteriological examination of the blood in the diagnosis of typhoid fever has become more and more appreciated. It has become a routine practice in some hospitals and has been found to be successful at an earlier stage than has Widal's test. The *American Journal of the Medical Sciences* for June contains an important paper on the subject by Dr. W. Coleman and Dr. R. H. Buxton. During the last six years they have bacteriologically examined the blood in 123 cases of typhoid fever and found the bacillus in 75 per cent. They draw 10 cubic centimetres of blood from a vein at the bend of the elbow and, following Conradi, they have abandoned broth and used ox gall as culture material with better results. A mixture is made of 90 cubic centimetres of ox bile, 10 cubic centimetres of peptone glycerine, and two grammes of peptone and is distributed into flasks in portions of 20 cubic centimetres and sterilised. Three flasks are used for an examination and about three cubic centimetres of blood are run into each. The flasks are incubated and on the following morning streaks are made from each over the surface of a litmus-lactose-agar plate. If microbes are present a growth may be observed in five or six hours. If the growth does not redden the medium and is found to be a bacillus resembling the typhoid organism it is tested for the Widal reaction with immune serum. Thus typhoid fever can often be diagnosed within 24 hours of drawing the blood. Dr. Coleman and Dr. Buxton have used this method in 34 cases. As a rule the blood was examined when a patient with fever for which there was no obvious cause was admitted to hospital. Six of the cases were ultimately found not to be examples of typhoid fever. Three ran the clinical course of typhoid fever but gave neither a blood culture nor the Widal reaction. In one case there was a difference of opinion as to the diagnosis. The remaining 24 cases were clinically typhoid fever and in all positive results were obtained by bacteriological examination of the blood. In cases of long duration examinations were made from the fifth to the twenty-first day of the disease. Previously 1602 cases of bacteriological examination of the blood in typhoid fever had been recorded. Of these 1197 (75 per cent.) gave a positive result. Of 224 examinations in the first week of the disease 89 per cent. were positive. The earliest positive result was obtained on the second day of the disease by Widal's test. Positive results become more frequent as the end of the first week is approached. Of 484 examinations in the second week 353 (73 per cent.) were positive. Of 268 examinations in the third week 178 (60 per cent.) were positive. Of 103 examinations in the fourth week 39 (38 per cent.) were positive. Of 58 examinations made after the fourth week 15 (26 per cent.) were positive. Some observers have obtained positive results from bacteriological examination of the blood in typhoid fever in 100 per cent. of the cases. Dr. Coleman and Dr. Buxton have obtained similar results since they adopted the bile-culture method. Hence they conclude that the bacillus is present in the blood in every case of typhoid fever and that failure to find it is due to defective technique. The diminishing percentages in the later weeks of the disease do not indicate that the bacillus has disappeared from the blood in the negative cases but point to diminishing numbers of bacilli which imperfect methods have failed to reveal. The bacillus appears to disappear about the time when the temperature falls to normal. This constant presence of the bacillus in the blood in typhoid fever modifies our conception of the pathology of the disease. It has been shown that the bacillus may flourish in the intestines of healthy persons who show no signs of the disease. Therefore, to produce typhoid fever the bacillus must grow in a situation whence it has free access to the blood. As the lymphatic glands and spleen contain enormous numbers of bacilli Dr. Coleman and Dr. Buxton suggest that the bacillus first finds its way from the alimentary canal to the lymphopoietic system where it develops chiefly and that thence it invades the blood stream. They think it doubtful whether it multiplies in the blood. According to this view its presence does not indicate a true septicæmia.

THE UNITED SERVICES MEDICAL SOCIETY.

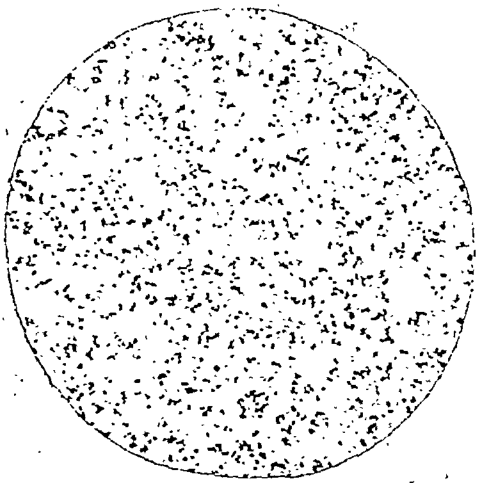
THE first meeting of the council of the newly formed United Services Medical Society was held on May 30th. It was decided that meetings should be held at the Royal Army Medical College at 8.30 P.M. on the second Thursday in each month commencing on Oct. 10th next; that the annual subscription should be 5*s*. payable in advance; and that a notification of the formation of the society, accompanied by an invitation to join, should be sent to all medical officers on the active lists and to those on the retired lists whose addresses could be discovered. Should any medical officer on the active or retired lists of the navy, the British and Indian armies, or the auxiliary and colonial forces not receive an invitation the council hopes that, if desirous of joining the society, he will communicate with one of the honorary secretaries, Fleet-Surgeon W. W. Pryn, R.N., "Tredown," 25, Idmiston-road, West Norwood, London, S.E., or Lieutenant-Colonel C. H. Melville, R.A.M.C., Royal United Service Institution, Whitehall, London, S.W.

"SALTED PLAGUE VACCINE."

AT a summer meeting of the Bombay Medical and Physical Society Dr. R. Row described some peculiar physical and chemical characters presented by bacillus pestis when grown at a temperature of 40° or 41° C. or in symbiosis with staphylococci. A plague culture grown under these conditions is sticky and glutinous, so that it is with difficulty scraped off the agar surface on which it is grown; but when it has been dislodged from its bed the whole culture can be easily gathered up on the platinum loop in the form of a bead owing to the gummy and cohesive nature of the mass. This sticky character of bacillus pestis grown at 40° or 41° C. contrasts strongly with that of a bacillus grown at the room temperature of 25° or 28° C. The cause of the difference in the two classes of cultures is that the growth at low temperatures is rich in chromatophile endoplasm with hardly any ectoplasm or "capsule," while that grown at higher temperatures is rich in the ectoplasm or capsule, the chromatophile granules being found only in small traces. This character of stickiness is also an index of the virulence of the culture, being present only in those of high virulence and absent in those of low virulence. A sticky plague culture when taken up in sterile water and allowed to stand for several days yields a uniformly opalescent fluid consisting of a sort of suspension or emulsion of the glutinous material entangling a few bodies of the plague bacilli. On addition of chloride of sodium even in excess to an emulsion of a sticky culture no precipitate is obtained until after several weeks' standing. This salted emulsion, therefore, not only gives a fluid rich in protein material but the presence of sodium chloride in excess renders the fluid sterile after a few days, so that a potent and at the same cuprous oxide. The solution constitutes a clear, colourless, watery liquid. Owing to the solvent power mentioned when reduction of the cupric oxide contained in the cupric test solution is effected in the presence of ammonia, the result is the loss of the blue colour derivable from the cupric oxide, and the production of a perfectly colourless, watery liquid. Reduction is in no way interfered with, but the reduced oxide fails to make itself visible. The action occurring is turned to account for quantitative sugar determination in the *application of the ammoniated cupric liquid which bears* my name. If the ammonia be driven off by means of heat the cuprous oxide previously held in solution becomes precipitated, but, as the forthcoming evidence will show, it falls in a state somewhat modified from that presented under precipitation in the ordinary way.

To illustrate the effect of the presence of ammonia a 3 per 1000 strength of dextrose solution is a convenient one for employment. It is requisite that there should not be sufficient sugar to stand in excess of the cupric oxide to be reduced in the test solution employed. Two cubic centimetres of the 3 per 1000 dextrose solution do not fully reduce the cupric oxide in two cubic centimetres of Fehling's solution and therefore a certain amount of the test liquid remains unchanged. The precipitate produced on boiling the proportions named of the two liquids by themselves consists, as may be inferred, of the normal red cuprous oxide. This is seen to be dispersed through the liquid and afterwards to settle as a compact red deposit in the ordinary way. Examined microscopically it is found to present the usual nodular condition with the nodules cohering into irregular-shaped masses. If to a corresponding admixture of test and dextrose solutions five drops of strong solution of ammonia (specific gravity 0·880) be added, considerable boiling is required before any notable reaction is seen to occur. The first effect noticeable is that the intensity of the blue becomes somewhat diminished as a consequence of the reduction without precipitation that takes place. Then, as the ammonia is driven off, the contents of the tube may become suddenly opaque and in the first instance of a dirty green colour, which quickly runs into dirty yellow and afterwards brownish with a certain amount of reddish tint. The precipitate to the naked eye presents a very different appearance from that of the precipitate belonging to the normal reaction, and microscopically it is seen to consist of conspicuously finer particles with seemingly a less strong cohesive tendency. A representation of the character of the precipitate is given in Fig. 3.

FIG. 3.



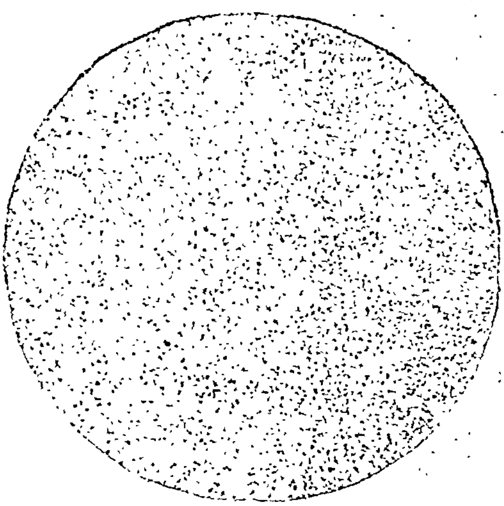
From photomicrograph of suboxide precipitate from two cubic centimetres of 3 per 1000 solution of dextrose, two cubic centimetres of Fehling's solution, and five drops of ammonia solution. Magnified 440 diameters.

Variations may be made in the strength of the sugar solution and the amount of ammonia with varying results as regards the colour of the product, and if enough sugar be present fully to reduce the cupric oxide of the test and enough ammonia to keep the suboxide formed in solution, the contents of the test-tube may be brought temporarily to a clear, colourless state, which with a further expulsion of ammonia suddenly changes and gives place to the presence of the suboxide in a precipitated form.

An instructive result is obtained by adding a little albumin to the admixture of Fehling's solution, sugar, and ammonia. Albumin has no reducing power in itself, and in small quantity (in large quantity it interferes with precipitation apparently through the extent of concurrent generation and evolution of ammonia occurring) exerts no influence on the character of the cuprous oxide precipitate produced. It is the normal red precipitate that falls in the presence of the albumin, just as happens without it, and microscopically the conditions *in the two cases are practically alike. If, however, the* ammonia and albumin are conjoined an effect is produced identical with what is noticed on applying the test to urine containing a slightly abnormal amount of sugar.

Taking two cubic centimetres of Fehling's solution, two cubic centimetres of a 1 per 1000 solution of dextrose, five drops of ammonia solution, and five drops of a 2 per cent. solution of dried egg albumin, and boiling in the usual way, the following is the result observed. Quite prolonged boiling is required before any change is perceived. Then the contents of the tube become milky and dark green, and, as boiling is carried on, the green passes into a lighter shade with a yellow tint. The condition agrees with what would be suggestive, if urine were being examined, of the presence of a slightly abnormal amount of sugar. By increasing the strength of the sugar solution to 2 per 1000 the reaction is of the same character, but more marked in degree. The microscopic appearance presented is totally different from that observed in ordinary circumstances and perfectly in accord with that belonging to urine exhibiting a similar kind of behaviour with Fehling's test. The field is studded over with exceedingly minute separated particles, so minute in the case of the 1 per 1000 strength of sugar solution as to require close attention to be given to see them. With a stronger solution they are more distinctly visible, but are still seen to be scattered in a more or less completely isolated state. The microscopic appearance fully accounts for the emulsion-like character belonging to the product. Fig. 4 gives a representation of the condition that has been described.

FIG. 4.



From photomicrograph of suboxide precipitate from two cubic centimetres of 2 per 1000 solution of dextrose, two cubic centimetres of Fehling's solution, five drops of ammonia solution, and five drops of a 2 per cent. solution of dried egg albumin. Magnified 440 diameters.

INFLUENCE OF URIC ACID.

I will now pass to the consideration of the part played by the cupric oxide reducing agents that are present in the urine in addition to sugar. The only agents of sufficient significance to call for attention are uric acid and creatinine. Let us see in what position these agents stand in relation to the matter that is under consideration, first dealing with uric acid.

Observation shows that uric acid behaves in a corresponding way to sugar in its reducing action upon Fehling's solution. The precipitate that falls consists of the red economical of heat as was often supposed because they imparted heat to the air which *immediately ascended to the* ceiling, objects in the room *remaining comparatively cold*. This was a process of heating by convection, whereas the action of gas fires depended on the much better system of heating by radiation which warmed the objects in the room rather than the air.

THE STUDY OF SPIROCHÆTÆ.

Schaudinn's observations upon the micro-organisms associated with the primary and secondary lesions of syphilis have acted as a powerful stimulus to the investigation of the genus spirochæta, alike by the student of pathology and by the protozoologist. But progress in this field of inquiry is still far from rapid, chiefly by reason of the small size and active movement of the majority of spirochætæ, for so great are the difficulties in the way of demonstrating details of structure, and so great are the difficulties of interpreting beyond possibility of question the appearances observed, that the data now at our disposal are still inadequate to dispose satisfactorily of even fundamental points. For example, the question of the position in nature occupied by spirochætæ is still a subject for discussion. Reproduction by longitudinal fission and the possession of a centrosome and of an undulating membrane are considered sufficient evidence by some observers of their title to rank in the animal kingdom, whilst others, relying on reproduction by transverse fission and the possession of diffuse nuclei and of flagella, would place them in the vegetable world, although a consensus of scientific opinion would at the present moment probably place the genus among protozoons rather than among bacteria. Again, the true relationship, if any, existing between spirochætæ on the one hand and trypanosomes on the other affords ample scope for speculative inquiry. In the meantime many of the facts that are accumulating so slowly are, as so often happens, derived from observations upon species which have no obvious and direct importance in medicine; nevertheless, the deductions drawn therefrom are of too great interest to be neglected. As a case in point we may mention some observations on spirochætæ derived from the oyster and from a British freshwater mussel, Anodonta cygnea (in which latter, by the way, they have not previously been noted as occurring), recently recorded by Fantham in the *Annals and Magazine of Natural History*. Dealing in the first place with the movements of these two species of spirochætæ—viz., spirochæta balbianii and spirochæta anodontæ, Fantham considers that the motion is resolvable into at least two components, the first a vibratory flexion of the body, mainly subserving the purpose of locomotion, and the second a spiral or corkscrew movement of the body as a whole, due to the winding of the membrane; this corkscrew motion is especially well seen in the case of spirochæta anodontæ, which has pointed ends. Compared with trypanosomes the spirochætæ seem to move more quickly and with an added corkscrew motion. Both the spirochætæ studied possess a spirally wound membrane, which is a lateral extension of the ectoplasmic periplast, a contradiction of the statements of Laveran and Mesnil who regard this structure as a loose investing membrane. The writer describes the undulating membrane as composed of longitudinally arranged "myoneme" fibrillæ, and it is these myonemes which set up the *transverse movements* in the surface of the body, manifested as waves passing down the body in a direction opposite to that in which the organism moves. The so-called "ciliate" (flagellate) stages in spirochætæ described by some writers Fantham regards as post-mortem products, for they are never seen during life, the apparent flagella or cilia being probably merely "myoneme" fibrils split off from the membrane during its rupture, which sometimes occurs during the violent contortions in the death struggles of the organism. Longitudinal fission is undoubtedly the more common form of reproduction, although observations are instanced which support the contention that transverse fission does actually take place; Fantham, however, apparently does not accept, at any rate in its entirety, Perrin's suggestion as to the presence of male and female forms. These observations are of very great interest and it remains to be seen how far the results obtained hold good for allied species and particularly for spirochæta pallida.

MODERN ALCHEMY: TRANSMUTATION REALISED.

Sir William Ramsay has promised to communicate to the Chemical Society shortly a full account of his researches on the radium emanation. The occasion will mark a great epoch in the history of chemical science since his investigations have shown that a given element under the powerful action of the radium emanation undergoes "degradation" into another. In short, the transmutation of elements is actually *un fait accompli*. We already know that helion appears as the radium emanation disappears, while when the emanation is in contact with, and dissolved in, water neon is produced but when in contact with a solution of copper salts the chief product is argon. More marvellous still is the fact that when copper salts are used lithium appears where before was no lithium. Copper is thus "degraded" to the first member of its family—i.e., lithium. For aught we know to the contrary, the time may ultimately come—over, of course, ages and ages—when the metallurgy of the world will be "degraded" to the alkaline metals. It would appear, therefore, that the noble metals are slowly breaking down and that gold, platinum, uranium, and other elements of high atomic weight will disappear and that their descendants will be the commonplace elements. This would seem to teach that gold and the other metals exhibiting high atomic weights have, after all, a complex and unstable constitution, the tendency of which is to resolve into simpler substances. These remarkable discoveries remind us again of the extraordinary prescience of the ancients, of the presentiments of the alchemists who evidently had some sort of a conviction that, after all, there is a primary matter from which all other elements are formed by various condensations. He is a bold man who nowadays confesses scepticism about anything. The world has seen men who have said "it is impossible." Generations have succeeded them who have seen the "impossible" come to pass.

THE RECOVERY OF RESIDUES FROM BRINE AND THEIR UTILISATION IN THE ROUTINE TREATMENT AT SPAS.

In The Lancet of July 28th, 1906, we referred in an annotation (p. 242) to an interesting communication which we received from Mr. F. Bale of Droitwich who drew attention to the fact that the ordinary scale which is produced in the brine evaporating pans contains certain mineral constituents which can be utilised with advantage in the routine treatment at spas. He stated that, amongst other things, the mother liquor contained the sulphates of calcium, magnesium, and sodium. If this liquor is diluted with water and salt scale added a mineral water is obtained effervescing, he says, with oxygen. We remarked that the disengagement of oxygen seemed to be singular and apparently proceeded from the dissolution of the hydrated sulphate of calcium, which is the chief constituent of the salt scale, although no chemical explanation of this production of oxygen gas was forthcoming. Mr. Bale now writes that there is no doubt that the gas evolved from the scale in water is oxygen or a gas rich in oxygen, as it gives all the reactions for power equal to a fourth of that of dextrose—in other words, it requires 40 milligrammes of creatinine to produce the amount of reducing action that is effected by ten milligrammes of dextrose. Under this reckoning the reducing effect on Fehling's solution produced by the one to two grammes, or about this, of creatinine conjectured to be eliminated per diem would count for exceedingly little in relation to the total reducing action exerted by normal urine, instead of occupying a position of significance, as there is a disposition to be assumed it does by some observers.

Calculating in the same way as was done for uric acid, the apportionment of the reducing power of normal urine to be assigned to creatinine comes out as follows: if 1·5 grammes of creatinine and 1500 cubic centimetres of urine be taken as representing the elimination amounts for the 24 hours the relation of creatinine to urine will stand at 1 per 1000. 40 milligrammes of creatinine, as shown above, may be taken as having the same reducing power as 10 milligrammes of dextrose. The reducing power therefore to be reckoned for the one gramme of creatinine is equivalent to $\frac{1 \times 10}{40}$ = 0·25 per 1000 expressed as dextrose. The mean total reducing power for normal urine was found to be 2·79 per 1000 expressed as dextrose, and, from the data given, 0·25 per 1000 of this, or practically one-eleventh, constitutes the proportion to be assigned to creatinine.

(To be continued.)

A CASE OF CEREBRO-SPINAL MENINGITIS DURING PREGNANCY.

BY J. D. WILLIAMSON, M.D., M.CH., M.A.O. R.U.I.,
PHYSICIAN FOR DISEASES OF CHILDREN AND OBSTETRICS, ULSTER HOSPITAL FOR CHILDREN AND WOMEN, BELFAST.

THE following are a few notes of a case of cerebro-spinal meningitis during pregnancy. It is interesting from more than one point of view: the age and condition of the patient, the onset of labour (whilst declaring that she did not know what was the matter with her and denying she was pregnant); the sudden onset of cerebro-spinal meningitis during labour, its rapid course, leaving no time for any very active treatment of service; the look of the patient; the character of the petechial and herpetic eruptions, without head symptoms; and the persistent vomiting, which in this case, at the time being associated with labour, did not demand the same amount of attention that in other circumstances it would have received.

The patient was in a neighbouring town up to Christmas, 1896, when she came home to Belfast to a street in a working-class locality. She was aged 13 years and 9 months; her mother gave the age in evidence at the coroner's court as 14 years on May 23rd, 1907. She was admitted on March 5th, 1907, to the maternity department of the Ulster Hospital for Children and Women as being in labour. The patient had always been a strong, healthy girl, well developed, and had never menstruated. The history of the case as reported to me was that on March 25th, about 2 A.M., the patient was seized with violent pains in the lower part of the back and abdomen, accompanied with vomiting; the pains were not continuous but paroxysmal; she became so ill that a medical man was sent for about 4 A.M. He prescribed medicine and advised certain measures to give her some relief; later he (the medical man) returned accompanied by another medical man, and on consultation both agreed that the patient was in labour. This the patient denied, protesting against anything of the kind. On telling her mother what was the matter the latter expressed her astonishment at anything of the sort as she never thought such a thing possible owing to her age and appearance. The patient absolutely refused to give any information regarding her condition to anyone. At 12 noon the patient was admitted to the Ulster Hospital. There was then a temperature of 101° F. and the pulse was 100, full, and bounding. There were strong uterine contractions at intervals of about ten minutes. There was no vomiting. There was slight mucoid diarrhœa, the cheeks were slightly cyanosed, and there was herpes about the nostrils and the mouth. No rash at this time was present; the tongue was furred but moist, and the pupils reacted normally. She had a wild and frightened appearance, was quite conscious, and complained of no pain in the head.

On vaginal examination the passage was moist and dilatable, the os was very slightly dilated, the presentation being a vertex but very high up in the pelvis. The patient remained in much the same condition until 2 P.M., when the pains became almost continuous, breathing was very rapid and distressed, the cheeks and lips were more deeply cyanosed, and the pulse was rapid and irregular. I was at this stage summoned by telephone to see the patient who was reported as being in the maternity ward and in labour. Almost immediately I received a second message to say that the patient was in a state of collapse and to come at once. I replied to give a hypodermic injection of strychnine and I would go over immediately, which I did and found the patient in bed lying on her right side, the legs flexed on the thighs, and the thighs on the abdomen; the forearm was flexed on the arm and both the arms were lying on the front of the chest; she was conscious, the pupils were slightly dilated and equal in size, the face was cyanosed, the breathing was rapid and difficult, the pulse was quick and irregular, and she was to all appearance in labour. She was nervous and frightened looking but did everything she was asked to do.

I got her turned over on to the left side and made a vaginal examination with some difficulty; the passage had the feeling as if contracting on the finger; the rugæ of the vagina were well defined. With some difficulty I reached the os, which was slightly dilated, admitting the tip of my finger. I was able to make out the presentation a vertex. With the left hand on the abdomen I could feel the uterus hard and contracting; her attitude and appearance did not harmonise in my opinion with the stage of labour and I felt that there might be something the matter in her chest. On examining the chest I arrived at the opinion that there was well-marked congestion of both lungs, the heart was acting rapidly and irregularly, and I was unable to make out any valvular lesion. No urine could be procured by catheter. Neither the face nor the extremities were œdematous. I also noted that she was very sensitive to the touch (hyperæsthetic). I got her turned on the back in order to examine the abdomen to learn if the child were still alive. The breasts were well developed, secondary areolæ were well marked, and there was a knotted feeling, and on pressure fluid exuded through the nipples. On stethoscoping over the uterus the fœtal heart sounds were heard very indistinctly and I observed some dark spots of a peculiar shape and appearance over the lower part of the abdomen and the thighs, which on investigation I learned had developed since her admission to hospital. The spots were dark in colour, irregular in shape and size, some flat, others raised like a small blister, and on pressure the colour did not disappear. These with her look and condition suggested cerebro-spinal meningitis. She, however, very quickly got worse though still remaining perfectly conscious, complaining only of the uterine contractions and pain in the back. There was no pain in the head but great pain and difficulty in swallowing, together with heavy breathing, death supervening about 3.50 P.M.

The patient's condition was so serious when I first saw her that I felt no obstetrical interference would prove of any service or obviate a fatal result to either mother or child; rapid dilatation of the os and removal of the fœtus might have been attempted but had I endeavoured to do anything of the kind death would have followed even more quickly and question, could I have saved the child had it been alive? Removal of the fœtus by Cæsarean section might have been adopted but I doubt very much if the child could have been saved.

In conjunction with Dr. J. Martin I made a post-mortem examination that night in the public mortuary. The body was stout, well built, well developed like a woman of small stature, and well nourished. There were no marks of any kind on the body other than the dark spotted rash (as described) over the abdomen and the thighs. Rigidity was well marked. On opening the skull the membranes of the brain were congested and the blood-vessels were full; also there was a greater quantity of serous fluid than ordinary in the cavity of the cranium. The brain was otherwise natural in appearance; there was more serous fluid than normal in the ventricles, and the internal blood-vessels were congested. The spinal cord was not examined; as the evidence of cerebro-spinal meningitis was so manifest we

English black rat) and mus decumanus (the English brown rat). Sketches of the heads and soles of the hind feet of several rats are shown for the purpose of better identification.

THE PLAGUE IN INDIA:

REPORTS ISSUED BY THE ADVISORY COMMITTEE APPOINTED BY THE SECRETARY OF STATE FOR INDIA, THE ROYAL SOCIETY, AND THE LISTER INSTITUTE OF PREVENTIVE MEDICINE.

THE Secretary of State for India early in 1905 placed the direction of an inquiry concerning some of the unsettled problems of plague with an Advisory Committee appointed by the India Office, the Royal Society, and the Lister Institute, acting in conjunction. The administration of an annual grant of money was also placed at the disposal of the Advisory Committee, which consisted of Surgeon-General A. M. Branfoot, C.I.E., as chairman, and representing the Secretary of State for India; the late Sir Michael Foster, F.R.S., and Dr. J. Rose Bradford, F.R.S., representing the Royal Society; and Colonel David Bruce, C.B., F.R.S., and Dr. C. J. Martin, F.R.S., representing the Lister Institute.

The Advisory Committee proceeded to elect a working commission consisting of the following: Major George Lamb, I.M.S., Captain William Glen Liston, I.M.S., Dr. G. F. Petrie, Mr. Sydney Rowland, Captain T. H. Gloster, I.M.S., Dr. M. Kasava Pai, Mr. V. L. Manker, Mr. P. S. Ramachandrier, and Mr. C. R. Avari. At the end of March, 1905, Dr. Martin started for India to organise the labours of the Commission, leaving six months later, when Major Lamb became the director of the work. In 1906[1] the first report of the work of the Commission was issued and the historical introduction was published in our columns. This was followed by sections dealing with the transference of plague by fleas, bugs, and other insects and, further, extremely interesting sections have now been issued dealing in the main with the connexion of rats with the spread of plague. We proceed to give a digest of these valuable reports:—

I.[2]—EXPERIMENTS UPON THE TRANSMISSION OF PLAGUE BY FLEAS.

I. (ii.). *Section A.—Transference from rat to rat by proximity without contact in the presence of fleas.*—This group of experiments were in repetition of those of Gauthier and Raybaud (1902–03) and showed that in the common Indian rat flea (Pulex cheopis, Rothschild) plague may be spread from an infected rat to a healthy rat confined in close proximity, but in such a way as to prevent contact with the body or excreta of the infected rat. This condition was obtained by a suitable arrangement of twin wire cages standing in a glass box which was covered with fine muslin; each cage stood in a separate tray, so that there could be no mixing of excreta from the two animals. Into one cage (X) was placed a rat inoculated with a plague culture obtained from the spleen of an infected guinea-pig, along with some 20 fleas obtained from Bombay rats. As soon as this rat was found dead a healthy rat was placed in the other cage (Y). The dead rat was left in the X cage until from 8 to 12 hours later, when it was removed and examined for septicæmia. If no plague bacilli were found in the blood microscopically the experiment was abandoned. If the healthy rat died a careful post-mortem examination was made, the position of the buboes was noted, and smears from the buboes, spleen, and heart's blood were examined. Cultures were made from the liver and heart's blood and tested on rats. All rats which had not died within three weeks of being placed in the Y cages were killed with chloroform and examined to make certain that they were not suffering from a subacute or chronic form of plague.

In Series 1 wild Bombay rats were used in both cages. The experiments were made in October and November—i.e., before the commencement of the epizootic or epidemic plague in Bombay. In all the 11 tests the healthy rat did not contract plague. It is noted that many Bombay rats are immune to small doses of bacillus pestis, and further that the tins under the cages did not in this series contain sand and that the consequent wetting of them with urine caused the fleas to die out quickly. It is considered that these factors vitiated the results of this series. In Series 2 of 16 experiments the inoculated rat was a Bombay rat, while the healthy rat was in all cases a white rat imported from England and kept isolated. No case of plague had occurred in these rats. In 11 out of 16 experiments (69 per cent) the healthy rat contracted plague. The full details of these experiments are given. No explanation of the negative experiments is suggested. In Series 3 Bombay rats were used in both cages and some of these rats may be considered to have been immune. They were caught in the houses and gullies of the city and isolated before use to prove their freedom from infection. In 50 complete experiments dealing with 35 house rats (Mus rattus) and 15 gully rats (Mus decumanus), 13 of the former (i.e., 37 per cent.) and six of the latter (i.e., 40 per cent.) developed plague. The report, assuming that 40 per cent. of Bombay rats are immune to the cutaneous injection of small doses of bacillus pestis, makes the percentage of positive results with susceptible animals to be 61 per cent., which approaches that of Series 2. "On 30 occasions, therefore, has a healthy rat experimentally contracted plague in sequence to living in the neighbourhood of a plague-infected rat under circumstances which prevented the healthy rat coming in contact with either the body or excreta of the plague-infected rat. In all cases a fairly abundant supply of fleas was present; these could pass freely between the two rats and, except for 'aerial contagia,' formed the only apparent means of communication between the animals. The presumption is that the plague was transferred from the sick to the healthy rat by the agency of the fleas." It was found impossible to perform control experiments in order to exclude aerial infection in the absence of fleas as this latter condition could not be certainly obtained.

Section B.—The next experiments dealt with the *transference of plague from rat to rat by the transference of fleas.* In these, Bombay rats were inoculated with a virulent culture of bacillus pestis, placed separately in flea-proof cages and supplied with rat fleas. In the event of any of these rats dying from plague and of their blood containing any bacillus on microscopical examination, the fleas were caught and transferred to a fresh flea-proof cage in which was placed a healthy rat. The flea-supply for each healthy rat was always obtained from two or more septicæmic rats. The same observations were made upon all the uninoculated rats that died as in the first series described above. All rats that had not died within three weeks were killed and examined. In Series 4 fleas collected from rats dead from the plague were transferred to healthy English white rats. In 8 out of 13 (61 per cent.) completed experiments the rats which received the fleas died from plague, while in five they remained healthy. The experiments are described in detail in the report. In Series 5 fleas were transferred from Bombay rats dead from septicæmic plague to healthy Bombay rats. Out of 25 completed experiments, 19 with Mus rattus and six with Mus decumanus, nine of the former species (i.e., 47 per cent.) and four of the latter (i.e., 66 per cent.) contracted plague. Allowing again 40 per cent. of Bombay rats to be immune to such a method of infection the percentage of positive results is raised to 87 per cent. In this section, accordingly, we read that "in 21 experiments out of 38 healthy rats living in flea-proof cages have contracted plague in sequence to receiving fleas collected from rats dead or dying of septicæmic plague in another cage. The possibility of the rat flea (P. cheopis) carrying plague from one rat to another is therefore demonstrated clearly."

I. (iii.). This deals with the experimental production of epidemics amongst guinea-pigs. In this research a highly ingenious series of small "go-downs" or cabins was designed by Lieutenant-Colonel W. B. Bannerman and Captain Liston and built under their supervision. They were of brick and mortar, with concrete floors on the top of a high plinth which were impervious to rats, and in each cabin was an inspection chamber separated by a screen of wire netting from an inner chamber for the animals under experiment, which chamber was separated from the roof by one or two layers of wire netting in the several huts. These also varied in the amount of light that was admitted to them, but the chief point of difference was in the construction of the roofs. In two these were made of ordinary country tiles, which were readily pervious to wild rats, two were made of Mangalore tiles, which were less pervious, and two of corrugated iron, which were entirely impervious to rats.

selection of "fly free" sites for the separation camps and for some provision by which treated natives may be kept under observation for considerable periods.

The atoxyl and mercury treatment lately used in our laboratories gives, when compared with atoxyl, fairly permanent results and if an atoxyl treatment should be undertaken in Uganda it would be advisable to start at once with this combined treatment, even if the reliability of this double treatment has so far not been fully established.

Summarising, we would like to suggest in the treatment of sleeping sickness: a fresh 20 per cent. solution of atoxyl, warmed up to 40°, to be administered in small doses to commence with and the doses to be gradually increased, not, if possible, passing the limit of one cubic centimetre of a 20 per cent. solution. The atoxyl to be followed as soon as possible by mercury in the form of sublimate and, in addition, some other trypanocide to be given; we would specially recommend fuchsin. We have lately tried a large number of colouring matters, both Ehrlich's and Mesnil and Nicolle's, and have come to the conclusion that fuchsin is the most promising. In addition to this, as was insisted upon by Thomas and Breinl, the general strength of the patient must be sustained in every way possible.

Liverpool.

CEREBRAL HYPERÆMIA AS A FACTOR IN THE THERAPEUTIC ACTION OF LUMBAR PUNCTURE.

(ILLUSTRATED BY A CASE OF TETANY.)

BY FRANK O. EVE, M.D. CANTAB., M.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL INFIRMARY AND TO THE VICTORIA HOSPITAL FOR CHILDREN, HULL.

IT has commonly been assumed that any benefit which may result from lumbar puncture is due solely to relief of intracranial tension. And when (as usually happens) the tension is not measured at the time of puncture, this is the natural assumption. During the past few years I have always measured[1] the intracranial tension during a lumbar puncture, and have been led to the provisional conclusion that relief of tension should be given therapeutic credit only in cases where the hypertension is considerable; and that where the pressure is normal or slightly raised the benefit which sometimes results from lumbar puncture should be ascribed to other causes. These causes may well be manifold, but I would like to advocate the predominant claims of one factor which, so far as I know, has not received attention. And that factor is the marked passive *hyperæmia* of the cerebro-spinal vessels which must inevitably result from the removal of any considerable quantity of cerebro-spinal fluid. For, owing to the uncollapsible bony envelope of the central nervous system and to the inextensibility of its nervous and liquid contents, it follows that for every ounce of cerebro-spinal fluid removed an exactly equal quantity of blood will be added to the contents of the cerebro-spinal vessels. In other words, an equivalent hyperæmia will be produced. And if, as is frequently the case, an ounce or an ounce and a half of fluid is withdrawn, the consequent engorgement of the vessels must be very considerable. For if at the end of the puncture the pressure is zero, it means that the venous pressure has pushed out cerebro-spinal fluid until the veins are distended to their natural limits. To regard this hyperæmia in another light, it is reasonable to suppose that the addition by lumbar puncture of one and a half ounces of blood to that normally contained in the blood-vessels of the brain and cord might almost double their normal blood quantum, though I do not know the exact amount of this. The brunt of the engorgement produced by puncture would certainly fall on the thin cerebral veins. How far the hyperæmia would affect the venous twigs and capillaries, and hence diminish the resistance and increase the blood-flow, could scarcely be decided except by experiments.

Illustrative Case of Tetany treated by Lumbar Puncture.

This case is recorded partly because it illustrates the above thesis that the therapeutic value of lumbar puncture is largely and sometimes solely due to the hyperæmia produced, and partly because I believe it to be a new treatment for a rebellious case of tetany which had resisted all other ordinary remedies.

The patient was a healthy boy, aged four years, who betrayed a neurotic constitution by nocturnal enuresis and by his capricious moods and his often anxious and fretful expression. The morbid excitability of his nerves was shown by the contraction of the circumoral muscles in response to mechanical stimulation of the seventh nerve by a penholder. The onset was acute and idiopathic a fortnight before admission, the mother noticing first a limp and then painful contractures of the hands and feet.

On admission walking was impossible owing to the contraction of the calf muscles, which drew up the heels two inches from the ground. The flexors of the forearms were also firmly contracted, producing flexion of the extended fingers and marked adduction of the thumbs. In other respects, including reflexes, appetite, and sleep, the child was healthy.

Treatment for 12 days consisted of tonics with open air (balcony) day and night. Then five days of aperients and vermifuges in response to a history of worms eight weeks previously. Next 11 days of energetic sedative treatment with chloral and bromide. The case had now a duration of six weeks with a month of hospital treatment without the slightest improvement, and there was the fear of the condition lapsing into chronicity. Encouraged by former success[2] in a few other refractory subacute cerebral conditions, I stopped all other treatment and tried the withdrawal of an ounce of cerebro-spinal fluid by lumbar puncture under chloroform. The pressure was normal (200 millimetres of water). Next day the child was more rigid, but from that time onwards improvement was rapid and complete. In three days the fingers could be voluntarily extended and in 12 days he could walk, but even after three weeks one heel would not quite touch the ground. The child was sent for a fortnight to the seaside and when finally inspected seven weeks after the puncture there was nothing to be made out except a scarcely noticeable tendency to adduction of the thumbs.

It will be noticed that in this case care was taken to eliminate the effects of bed and hospital environment. It will also be noted that ordinary remedies were ineffectual and that the contracture was in a stationary condition. The case convinced me therefore as strongly as any single therapeutic observation could, that the withdrawal of an ounce of cerebro-spinal fluid was responsible for the cure of this child. And since the pressure was normal, it seemed legitimate to conclude that it was the *hyperæmia* which had favourably affected the nutrition of the disordered nervous tissues in somewhat the same favourable manner as it has been shown by Bier[3] and others to act in more accessible regions of the body.

In view of the almost harmless nature of lumbar puncture under suitable conditions, it seems justifiable to try it in a variety of acute or subacute cerebral affections which have resisted other treatment or are tending to become chronic. But until its indications are better understood lumbar puncture could scarcely be advocated until other remedies had failed.

Hull.

Medical Societies.

THE SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Piroplasma Canis.—Exhibition of Specimens.—Life Cycle of the Parasite of Sleeping Sickness.—Parasitic Protozoa observed in Africa.—Treatment of Trypanosomiasis.

A MEETING of this society was held on July 10th, SIR PATRICK MANSON, the President, being in the chair.

Dr. J. W. W. STEPHENS of the Liverpool School of Tropical Medicine showed specimens prepared by Captain proportion of each species in different localities, by the Hon. N. Charles Rothschild, M.A., F.L.S.

[2] Ibid.

[3] The hyperæmia of lumbar puncture would not be quite analogous to that of Bier's method, which in the case of the head would be produced by a ligature round the neck. Presumably this would produce engorgement of the cerebral veins when sufficient cerebro-spinal fluid had been gradually expelled, but it would be accompanied by increased cerebro-spinal pressure and a diminished blood flow owing to the embarrassment of the venous return.

III.—This paper is a careful and excellently illustrated description of the Physiological Anatomy of the Mouth Parts and Alimentary Canal of the Indian Rat Flea (Pulex cheopis, Rothschild).

IV.—This paper describes an experiment made to discover the Effect upon Virulence of the Passage of Bacillus Pestis through Rats, by subcutaneous inoculation of infected spleen pulp from one to another, without intermediate culture; this *was done to test* a statement that such a passage of infection was a matter of great difficulty, and that the organism loses virulence in the bodies of rats, an intermediate host being necessary for the maintenance of an epizootic. This statement is opposed by the result of the experiment, which gave no evidence that the passage of plague from rat to rat is accompanied by any decrease of virulence. 26 such passages were effected without recourse to artificial media. Evidence was, however, obtained of the varying susceptibility of the Bombay rat.

V.—This deals with a variation of the preceding experiment, the infected spleen pulp being inoculated cutaneously, after scarification of the abdominal skin (in a manner similar to ordinary "vaccination"). It was found that a large percéntage of Bombay rats are immune to this method of inoculation. Out of 580 rats 239 died from plague, whilst 341 were alive and well after 14 days—that is, 50 per cent. were immune to this method. No alteration in virulence was noted.

VI.—A Note on the Immunity of Bombay Rats to the Subcutaneous Injection of Plague Cultures, dealing with two series of experiments made during 1904 and 1906 respectively. They prove that at the latter period the Bombay rat was no more susceptible to plague than at the former.

VII.—This paper is on the Infectivity of Floors grossly Contaminated with Cultures of Bacillus Pestis. The floors used in the experiments were of two sorts: (*a*) of ordinary cow-dung plastered, when moist, on the top of earth which had previously been beaten down; and (*b*) of "chunam," which is a mixture of sand and lime, put down moist and allowed to set. The report thus summarises the results: (1) Floors of cow-dung grossly contaminated with bacillus pestis remain infective for 48 hours, the infectivity being tested by rubbing scrapings into susceptible animals; (2) floors of "chunam" similarly contaminated do not remain infective even for 24 hours; (3) floors of cow-dung similarly contaminated remained infective for 12 hours but not for 24 hours to susceptible animals which were allowed to run about freely on them; and (4) under similar conditions floors of "chunam" remained infective for six but not for 12 hours.

VIII.—This section is on the Number of Plague Bacilli in the Blood, Urine, and Fæces respectively of Rats which had Died from Plague. It is thus summarised. "The blood of plague-infected rats may contain an enormous number of plague bacilli, even as many as 100,000,000 per cubic centimetre having been found before death. On the other hand, rats occasionally die from plague with little or no septicæmia. An insect sucking the blood of most rats shortly before death would imbibe a large number of bacilli. While the blood of a rat may have so many bacilli the urine may have none at all, or at least less than 10 per cubic centimetre. Plague bacilli were discovered in the urine in 29 per cent. of the cases. When the urine does contain plague bacilli they are always present in much fewer numbers than in the blood. The fæces of rats dead of plague, the blood of which contained abundant bacteria, are not highly infective and would appear to play little part in spreading the epizootic."

IX.—This paper deals with the Quantitative Estimation of the Septicæmia in Human Plague. The results of the investigation on which it was founded are as follows. 74 examinations of specimens of the blood from 28 patients were made. Bacillus pestis was found in 16 fatal cases. It was not found in seven fatal cases nor in five cases that ended in recovery. It is further noted that microscopic examination of the blood cannot be regarded as a trustworthy criterion of the degree of septicæmia. This may be present, however, at a comparatively early stage of the disease and for a considerable number of hours before death, and the septicæmia may be of an irregular or fluctuating type.

X.—The last investigation with which this report deals is on the important epidemiological point of the Existence of Chronic Plague in Rats in Localities where Plague is Endemic. During one month 1800 rats were caught alive in two villages where plague has recurred annually for three years without discoverable reinfection, but at the time the rats were caught, with one exception, there was no active plague in the villages. In seven of the rats, although they all seemed healthy when alive, chronic abscesses were found in the abdomen from which bacillus pestis was in each case cultivated. The situation of the lesions seems to point to an intestinal infection. The organs were apparently normal and there was no emaciation. Of the animals inoculated directly from, and with subcultures of, the abscesses only one survived.

The next series of reports are in continuation of those just summarised and previously published in the *Journal of Hygiene*. They are published in the same journal[3] and they contain the results of observations and experiments made in the laboratory. The following papers are now issued:—

XI. *On the diagnosis of natural rat plague*.—During 16 months' work the Commission examined about 150,000 rats, of which 19,000 proved to be plague-infected. The post-mortem records of 4000 of these plague rats have been carefully analysed. The writers consider that the most important naked-eye signs by which plague may be identified are: the presence of a bubo (present in 85 per cent.); the presence of general subcutaneous congestion, with hæmorrhages both under the skin and in the organs; a "granular" liver in which the surface of the organ is dotted over with minute white or grey specks; and an abundant clear pleural effusion. The size and appearance of the spleen were found to be variable and of subsidiary diagnostic import. In the earlier part of the work great importance was attached to microscopical examination of smears of the blood and organs. Subsequent experience, however, coupled with experiments with inoculated and normal rats carefully devised to test the skill of the examiners, convinced the writers that naked-eye examination by an experienced observer is more satisfactory for purposes of diagnosis than microscopical examination alone. Naturally in isolated cases both methods must be employed, but the results clearly show that the omission of the routine microscopical examination of every rat in an investigation conducted on a large scale does not necessarily impair the accuracy of the work, while the saving of labour is, of course, very great. The bubo is shown to be the most important structure to examine microscopically. Thus out of 1000 plague-infected rats with buboes plague bacilli were by microscopical examination found in the bubo of 991, in the spleen of 901, and in the heart-blood in only 375. The inoculation of suspected material upon the shaven abdomen of the guinea-pig has proved of the greatest value for diagnosis; the method appears to fail only in about 2 per cent. of fresh, and about 10 per cent. of putrid, rats. In this connexion the writers point out that the bacilli found in naturally infected rats are fully virulent, 62 per cent. of the inoculated animals dying from acute plague in five days or less. No disease of the rat was met which caused any material difficulty in diagnosis.

XII. *The pathological histology of the spleen and liver in spontaneous rat plague* has been examined by Dr. J. C. G. Ledingham of the Lister Institute in material collected by the Commission in Bombay. In the spleen the incursion of bacillary swarms produces in the early stages extensive hæmorrhages, congestion of the pulp sinuses, and perinodal areas of necrosis. In later cases definite abscess formation occurs and is accompanied by extensive reaction on the part of the plasma cells which form a barricade separating the lymphoid tissue of the node from the necrotic zone. The bacilli are very rarely found in the interior of the nodes, yet karyorrhexis of the nodal cells is frequently far advanced through a toxic action. In the liver focal necroses may be so numerous that little healthy liver tissue remains. Bacilli are nearly always found in the central capillaries of these foci and actual bacillary embolism was frequently noticed. In some cases no free bacilli were demonstrable, all the organisms having been taken up by endothelial cells which appear to be largely responsible for the removal of the bacilli. The writer also notes the occurrence of giant cells of Langhans' type in the neighbourhood of necrotic foci.

XIII. *Transmission of plague by feeding rats with infected material*.—During the last ten years in which plague has been experimentally investigated much work has been done worth perusal by ophthalmologists as introducing them to the more recent work, chiefly in Germany, on the bacteriology of corneal ulceration, and this is probably the chief service which it may be expected to render. The printing, otherwise good, is marred by several misprints and some errors in spelling.

---

Modern Methods of Diagnosis in Urinary Surgery. By EDWARD DEANESLY, M.D., B Sc. Lond., F.R.C.S. Eng., Honorary Surgeon, Wolverhampton and Staffordshire General Hospital. London: H. K. Lewis. 1907. Pp. 97. Price 3s. net.

THE want of a brief and concise *résumé* of the modern methods of localising and distinguishing surgical diseases of the urinary organs has long been felt. This gap in scientific literature has now been adequately filled by Dr. Deanesly's little book. The work is based on a large clinical experience and is intended rather for the general surgeon than for the urinary specialist. The first chapter on the interpretation of urinary symptoms contains much information that is extremely useful. The author classifies these symptoms under the following headings: (1) disorders of micturition; (2) pain referred to some part of the urinary tract; (3) abnormal conditions of the urine; and (4) palpable enlargements or malformations of affected organs; and subsequently he clearly points out the significance of each and indicates the deductions to be drawn in arriving at an accurate diagnosis. The discussion of abnormal conditions of the urine is rightly relegated to a separate chapter which concludes with a description of the methods employed in gauging the functional value of the kidneys. Dr. Deanesly emphasises the importance of separation of the urines and for this purpose advocates the use of Luys's segregator which, he maintains, is quite as accurate as the ureteral catheter and above all free from the danger of infecting the kidneys. The chapter on the differential collection of specimens of urine is a very valuable one and full of practical hints. As might be expected in a work of this nature the cystoscope receives its full share of attention. The author favours Nitze's instrument and after describing its general principles gives detailed instructions for its use. This little book, besides being well written, is essentially practical and should prove a welcome addition to the library of the practitioner and general surgeon.

Functional Nervous Disorders in Childhood. By LEONARD G. GUTHRIE, M.A., M D. Oxon., F.R C.P. Lond. (Oxford Medical Manuals.) London: Henry Frowde and Hodder and Stoughton. 1907. Pp. 300. Price 7s. 6d.

JUST as the last quarter of the nineteenth century was marked by a remarkable advance in our understanding of the diseases of infancy and childhood, so now in the first decade of the twentieth century medical interest—and not only medical interest—centres in the physiological aspects of the developing child. These aspects are certainly rendered all the more intelligible by the light which pathology throws upon them. In his work on "The Functional Nervous Disorders of Childhood" Dr. Leonard Guthrie elucidates many of the perplexing problems involved in the study of the normal child by devoting considerable attention to that large class of borderland cases which are generally described as neurotic and which, strictly speaking, cannot be called either physiological or pathological. The management of these cases is of equal interest to the physician, to the psychologist, and to the pedagogue, and it is difficult to say to whose jurisdiction they should be most properly referred. It is a mere truism to say that the neurotic child is the subject *par excellence* of functional nervous disorders, but the neurotic child is the most interesting of all children for the reason that from him most is to be expected and from him most to be feared. Owing to the nervous instability which is characteristic of the class the most trivial physical stimuli produce the most disproportionate effects; this makes such children difficult to manage, physically and mentally. No one, as Dr. Guthrie remarks, would deny that a certain leaven of the neurotic element is "the spice of life"; the creative faculty in art, science, and literature depends on imagination and upon emotional susceptibility, but the neurotic temperament which combines these qualities requires the most judicious and sympathetic handling during the period of early development. As Dr. Guthrie tells us, "The lives of men and women such as Wagner, Berlioz, Charles Lamb, Charles Dickens, Carlyle, George Eliot, and many others were embittered and their genius trammelled by cerebral and gastric neurasthenia," and this through "want of sympathetic and judicious treatment in their youth." How many "undiscovered millions" remain in obscurity to-day from the same cause? Parents, the author tells us, are now fully alive to the influence of mind upon disease, and they desire to know how hereditary tendencies to moral failings as well as to disease may be counteracted. "Hence," he continues, "our professional armamentarium is no longer completed by a set of infallible prescriptions for coughs, worms, stomach-ache, and fits. ...... We are expected to use our knowledge of the characteristics of such children and to back our medical advice with common sense in treating them." For any child or any individual to be a success he must remain in harmony with his environment, but it is difficult for the neurotic child to remain at peace with his surroundings, for he is so susceptible to every change that occurs in them; if he fails to remain in harmony, it may be either the fault of the environment or the fault of his organisation, and if it be the latter the further question has to be considered, Is this due to hereditary and unpreventable causes, or to conditions over which the human will has control?

In dealing in various ways with these questions the author is faced *ab initio* with the problems of heredity. If acquired characteristics of the mind or of the body cannot be transmitted in descent, the progress of human evolution can only be advanced by means which are directly or indirectly dependent on selection, whereas a prospect of unbounded optimism at once opens up if we can convince ourselves of the truth of the alternative hypothesis. It is a very curious fact that Virchow should have admitted the possibility of the transmission of acquired pathological characteristics, while he denied the same right to those which were physiological. The truth or the falseness of the general postulate (whether acquired characteristics can be inherited or not) is, as Herbert Spencer contended, of the utmost importance to mankind, for according to the manner in which we regard this question so are determined our actions in politics, ethics, sociology, and, we may add, in medicine. Dr. Guthrie wisely touches but lightly on this controversial question: he confines himself more profitably to the other aspect of the question—namely, how to find the best possible environment for the child, and especially the neurotic child, be his hereditary or congenital faults what they may.

It is impossible in the limits of a short review to follow the author in his discussion of the many aspects of the management and recognition of the functional neuroses and psychoses of childhood. In the early chapters he moralises on the unnecessary sorrows of childhood, the fears of the neurotic child, his frettings and home sicknesses. He describes the disorders of sleep, their causes and treatment; then he points out the moral failings of a child with "a temperament" and blames the pedagogue or parent who submits him to mental overstrain or galling discipline. The more definite medical aspects are dealt with in the concluding chapters in which the disorders of the sympathetic nervous system come first and present a goodly array of symptoms. Then enuresis, "reinforced concrete"; in consequence of this these go-downs remained absolutely free from fleas, so that a number of clean contact experiments were obtained.

Five guinea-pigs inoculated with plague were confined in one of the go-downs with 25 healthy animals. It is shown that the healthy animals never contract plague in the absence of fleas, though living, in some instances for several weeks, in close contact with plague-infected animals. In the huts which were not flea-proof the epidemics of plague were shown to progress differently at different seasons of the year. In the height of the prevalence of epidemic plague the progress was very rapid, while in the off-plague season the infection travelled more slowly through the healthy guinea-pigs and in some cases killed only a portion of them. It is shown that the progress of the epidemic among the guinea-pigs is proportional to the abundance of fleas and that the explanation of its seasonal variation is probably to be found in the effect of seasonal influences on the prevalence of these insects. Another series of experiments shows that in go-downs containing plenty of fleas animals do not contract plague if they are protected by being suspended in mid-air or by a cage of wire gauze impervious to fleas.

XVII. *Experiments in plague houses in Bombay.*—In a paper published in the first report and summarised above there were detailed a number of observations which were carried out in plague houses. During the epidemic of 1907 these observations have been confirmed and amplified. Guinea-pigs were allowed to run about in plague-infected houses overnight; in 18 out of 100 experiments the animals subsequently died from plague. Fleas caught on guinea-pigs or rats in plague-infected houses were transferred to healthy guinea-pigs in flea-proof cages in the laboratory; in 34 experiments these animals died from plague in 14 instances (41 per cent.). By using guinea-pigs as flea-traps an estimate was made of the abundance of fleas in different houses. Houses proved to be plague-infected were found to yield 12 times as many fleas as houses which were not plague-infected and three times as many as those which were only suspected of being plague-infected. Of 130 fleas dissected 32 per cent. were found to contain abundant plague-like bacilli in their stomachs.

XVIII. *On the external anatomy of the Indian rat flea (Pulex cheopis) and its differentiation from some other common fleas.*—This paper gives a detailed account of the external anatomy of the rat flea, with two illustrative plates. A third plate shows the cat, human, and other fleas, and the points by which Pulex cheopis may be distinguished are dealt with. The writers consider that Pulex cheopis is identical with Pulex pallidus, Pulex murinus, Pulex philippinensis, and several other species which have been described.

XIX. *On the natural occurrence of chronic plague in rats.*—In continuation of a previous note the writers describe 45 cases of localised encapsuled abscesses containing virulent plague bacilli which they have met with in Mus rattus in the Punjab villages. In 27 instances these abscesses were in the situation of peripheral lymphatic glands and may probably be taken to represent the remains of buboes; these cases occurred chiefly during the period of the decline of the epizootic of acute plague. In the remainder, however, they were situated in the spleen (12), the mesentery (5), or the liver; and these animals were found in the interval between the epizootics. The rats were in all cases trapped alive and appeared to be healthy. In Bombay only one such case has been met with in 19,000 plague-infected rats, while in the Punjab these examples of chronic plague account for more than 10 per cent. of all rats found infected. While pointing out that these localised abscesses are the only place where plague bacilli are known to occur during the off-plague season in the Punjab, the writers can find no direct evidence that such a condition ever lights up into an acute septicæmia and, chiefly on anatomical grounds, express their doubts as to whether it can be a source of origin for the acute epizootic.

XX. *A note on man as a host of the Indian rat flea.*—The experiments described above, and since repeated with similar results, afford ample confirmation of the observation of Simond (1898) and of Gauthier and Raybaud (1902, 1903) that plague may be transmitted from rat to rat by the agency of rat fleas. The direct experiment to show that plague can be conveyed in the same way from rat to man can never be made, and the inferential transference of the results of the experiments on rats to the spread of human plague has been not a little opposed, notably by Galli-Valerio (1900, 1903), on the ground that rat fleas do not bite men. This may be true of the fleas (Ceratophyllus fasciatus and Ctenopsylla musculi) commonly found on rats in Western Europe, but Gauthier and Raybaud (1902, 1903) in Marseilles and Tidswell (1903) in Sydney obtained direct evidence to the contrary with regard to Pulex pallidus (= Pulex cheopis), and Liston (1905) found that Pulex cheopis in Bombay readily attacks man during the plague season. The present Commission has made many observations which show that Pulex cheopis will make use of man as a host and may be captured in large numbers on men in plague-infected houses.

One of the methods employed was the following. About 40 fleas, caught on wild Bombay rats, were placed in a wide-mouthed jar which had a little sand at the bottom. Twice daily a man's hand and forearm were introduced into the jar and left in for 15 minutes each time. Fleas which crawled up the forearm were gently pushed back before they could escape. It was observed that the fleas bit readily and the man himself was soon cognisant of the fact. About every ten days the sand was removed and fresh sand substituted, so that multiplication of the original fleas by breeding was excluded. Five experiments in all were done after this method with the following result.

Experiment 1.—One flea was found alive on the twenty-fourth day.

Experiment 2.—One flea was found alive on the ninth day. In this experiment the sand had not been washed and there was present a fine dust, which by blocking the tracheal openings was probably prejudicial to the lives of the fleas. They were often observed to be dusted over with this material.

Experiment 3.—One flea was found alive on the twenty-fifth day.

Experiment 4.—One flea was found alive on the twenty-fifth day.

Experiment 5.—One flea was found alive on the twenty-seventh day.

From the above experiments it is seen that it was possible to keep rat fleas alive for nearly four weeks by feeding them on human blood. There was a considerable mortality during this time, but the main facts stand out (*a*) that they fed readily on man and (*b*) that some of them were still alive after 25 days.

It may be mentioned that rat fleas kept in similar circumstances, but without food, never survived longer than one week.

The following observations, which were carried out in a building which was unusually severely stricken with plague, are also of interest in this connexion:—

1. April 17th.—40 fleas were caught on a man who went into one of the rooms for a short time. They were all Pulex irritans.

2. April 18th.—113 fleas were caught on a man who entered one of the rooms. The species were as follows: Pulex irritans, 55; Pulex cheopis, 51; and Pulex felis, 7.

3. April 19th.—76 fleas were caught on a man who entered one of the rooms for a short time. The species were as follows: Pulex irritans, 40; Pulex cheopis, 34; and Pulex felis, 2.

4. April 20th.—80 fleas were caught on a man who entered one of the rooms. The species were as follows: Pulex irritans, 18; Pulex cheopis, 60; and Pulex felis, 2.

Thus, in three out of four rooms of this chawl, which was badly infected, abundant rat fleas were taken on the legs of men who entered the rooms only for a short time.

The results of the analysis of the extensive epidemiological observations of the Commission in the villages of Bombay and the Punjab have still to appear.

PUBLIC HEALTH AND BACTERIOLOGICAL RESEARCH LABORATORY FOR WOMEN MEDICAL PRACTITIONERS.—The governing board of the Middlesex Hospital has added to the medical school a laboratory which will be devoted entirely to the use of women medical practitioners for obtaining instruction for the examinations for the diploma in public health and of women students generally for the purposes of research work in bacteriology and general pathology. The new laboratory, which is on premises in Mortimer-street adjoining the Middlesex Hospital, is fully equipped for 12 workers and will be under the charge of Mr. A. G. R. Foulerton, director of the bacteriological and public health department of the Middlesex Hospital Medical School, with Miss Hilda K. Whittingham, M.B. Lond., as demonstrator.

diseases of the pulp and of the periodontal membrane. We still think that if the accounts of the various diseases were extended the value of the book would be considerably enhanced.

Health, Work, and Recreation. By G. A. HAWKINS-AMBLER, F.R.C.S. Edin. Liverpool: D. Marples and Co. 1907. Pp. 64. Price 6*d.* net.—The author of this little pamphlet has had previous experience in writing for a non-medical circle of readers. He writes easily and breezily, although some may think that his delight in a smart phrase occasionally leads him to transgress the limits of good taste. Mr. Hawkins-Ambler takes for his motto "In medio tutissimus," for he vigorously denounces the cranks who are ranged on both sides of the great hygiene controversies of the day. His most revolutionary doctrine is an attack on the "fetich of the cold bath" for everyone in all seasons. We agree with him that in winter all those who fail to "react" thoroughly to this time-honoured method of ablution are wise to replace it by a short stay in a hot bath, which they may follow by a cold or tepid sponge down. Mr. Hawkins-Ambler advocates nine hours' sleep for the average busy brain-worker. Quite the best advice in his book is contained in his last chapter on recreation, especially in that part which urges on the heads of families their great responsibility in maintaining a cheerful comradeship in the home circle; it is a theme that might well be enlarged upon with great advantage to both fathers and sons. The book is unfortunately carelessly constructed; thus we read in one chapter that the noise of the tramcars keeps the town dweller wakeful and in the next that it hushes him to sleep. The author perhaps deserves sympathy in the marring of a pretty peroration by the misprinting of "Prosperino" for "Proserpina" and "moon" for "noon." On page 61 he writes: "Times of fasting and seclusion were aforetime prescribed by the Church." They are still so prescribed.

JOURNALS AND MAGAZINES.

The Dublin Journal of Medical Science.—The July number of this journal contains an interesting communication from Dr. A. Francis Dixon, in which he offers an ingenious explanation of the necessity for the crossing of the great motor tracts in the central nervous system; he attributes the idea to a conversation once held with Professor G. D. Thane. The theory is founded on the fact that the right half of each retina is connected with the right occipital lobe which is accordingly concerned with the left half of the field of vision; it is reasonable that in animals with binocular vision the side of the body in relationship with the left field—i.e., the left arm and leg, and so on—should be connected with the right cortex which also governs that field of vision. This visual theory is supported by a few observations in comparative anatomy. It is illustrated by a useful plan. The same number contains a careful study of Splenic Enlargement and its Influence on the Blood, by Dr. T. Louis de Courcy, which formed the thesis for his doctorate at the University of Dublin.

The British Journal of Tuberculosis.—The third number of this journal is especially devoted to children and treats largely of the sociological side of the great problem of tuberculosis. There are special articles on the Preservation of Children and Adults from Tuberculosis in America, by Dr. S. A. Knopf of New York; Measures Employed in Germany for the Prevention and Treatment of Tuberculosis in Children, by Dr. Adolf Baginsky of Berlin; and on the Protection of Children from the Disease in Scotland and Ireland, by Dr. H. Hyslop Thomson and Sir John Byers respectively. A discussion by many authorities on Tuberculosis and the Child brings forward some important points and the number concludes by noticing several institutions for the treatment of the disease.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

TIODINE (COGNET).

(ROBERTS AND CO, 76, NEW BOND-STREET, LONDON, W.)

TIODINE is being introduced as an organic iodine compound suitable for administering iodine by injection. It contains very nearly half its weight of iodine. Tiodine is a colourless liquid with a somewhat alliaceous odour. As will be seen from its formula, which is $C_6SN_2H_{13}I$, sulphur is present and its chemical name is thiosinaminethyliodide. Tiodine is soluble in water, is neutral in reaction, and yields abundance of iodine on adding to it an oxidising substance, such as peroxide of hydrogen. It is supplied in pills or in glass bulbs. It is said to be administered without the symptoms known as iodism appearing, even when injected subcutaneously. It has been employed in the treatment of rheumatism, scrofula, and diseases of the respiratory organs.

DIAMALT PREPARATIONS.

(THE BRITISH DIAMALT CO., 11-13, SOUTHWARK-STREET, LONDON, S E.)

Two preparations, the one in liquid and the other in dry form, have been submitted to analysis with the following results:—DiaMalt liquid: moisture, 23·75 per cent.; mineral matter, 0·75 per cent.; malt sugar, 59·48 per cent.; protein, 5·88 per cent.; and dextrin, 10·14 per cent. In regard to diastasic activity, this preparation was found to digest five times its weight of starch in half an hour, 20 times its weight in one hour, and over 40 times its weight in three hours. The dry DiaMalt gave the following results: moisture, 1·00 per cent.; mineral matter, 1·90 per cent.; malt sugar, 83·20 per cent.; protein, 5·20 per cent.; and dextrin, 8·70 per cent. This preparation also was found to contain active diastase. In half an hour it digested its own weight of starch, in one hour two and a half times its weight of starch, and in three hours five times its weight of starch. The dry preparation consists of a crisp crystalline powder practically entirely soluble in water. The taste is pleasantly malty. The nourishing quality and digestibility of malt sugar are well known, and this carbohydrate is supplemented in these preparations by proteins and dextrin. The mineral matter consisted chiefly of soluble phosphate. The preparations are evidently obtained with great care from superior maltings, as is evidenced by the excellent flavour of the preparations and by the fact of their containing active diastase.

STERILISED MILK (DIAMOND REEF BRAND).

(STONE AND SON, MONUMENT BUILDINGS, LONDON, E.C.)

The analysis of this milk showed it to be of the same rich quality as that derived from the Guernsey cow. The results were as follows: fat, 5·05 per cent.; milk sugar, 4·80 per cent.; protein, 3·65 per cent.; and mineral matter, 0·72 per cent. The proportion of fat is very satisfactory, the solid matters altogether amounting to 14·12 per cent., which is quite 2 per cent. over the average. It is stated that the milk is sterilised by a special process. The process must be good, since the flavour characteristic of raw milk has not been spoiled. The milk was perfectly fresh and sweet and free from antiseptics.

EXTRA STOUT.

(WILLIAM DULLEY AND SONS, LTD., BREWERY, WELLINGBOROUGH.)

According to our analysis this stout represents a highly nourishing malt liquor. It contains no less than 9·67 per cent. of extractives, 6·61 per cent. of which are due to proteins. The alcoholic strength was 5·87 per cent. by weight, or 7·32 per cent. by volume. The mineral salts amounted to 0·25 per cent. and consisted chiefly of phosphates extracted from malt. The flavour was soft and for whilst the mortality from this disease in the urban districts of England averages 1483 per 1,000,000 it does not exceed 849 per 1,000,000 in the rural districts. The disease is everywhere more fatal to the male sex than to the female. As a means of tracing the relation of season to pneumonia fatality the official records for extra-metropolitan England afford no assistance, but the method adopted by the Registrar-General of publishing weekly returns for London offers exceptional facilities for this purpose. Taking the average of the last five years, it appears that in the metropolis 62 per cent. of the deaths from this disease occur in the first and last quarters of the year, taken together, whilst in the remaining half of the year the proportion does not exceed 38 per cent. Another condition of great importance from a public health point of view is that which is known as "puerperal fever," a name disapproved by the Royal College of Physicians—the proper designation being "puerperal septicæmia" or "puerperal pyæmia." The mortality from puerperal fever and other accidents of childbirth has not varied greatly in the course of the last 40 years. In the decennium recently closed the rate was equal to 295 per 1,000,000 of the female population at all ages, married and unmarried together. Expressed in terms of registered births, the ratios in the last four decennia have been 4·69, 4·75, 4·73, and 5·09 per 1000 severally. The mortality was therefore somewhat higher in the recent ten-year period than in any of its three predecessors. This increase, however, is almost certainly due partly to improved certification and partly to the system of inquiry before referred to.

The report before us contains highly interesting references to the behaviour in recent years of certain other prevalent and very destructive diseases; more especially to the several forms of tuberculosis, to cancer, and to the vastly important subject of infantile mortality. In the present article no space remains for adequate notice of these subjects, but we hope to return to their consideration on a future occasion.

THE NEW BUILDINGS OF ST. BARTHOLOMEW'S HOSPITAL.

ON July 23rd His Royal Highness the Prince of Wales opened the new departments for out-patients at St. Bartholomew's Hospital. The Prince, who is President of the hospital, was accompanied by the Princess and on arrival at the hospital at about 3.30 P.M. was received in the Great Hall by Lord Ludlow (the treasurer), the almoners, Dr. Norman Moore as senior physician, Mr. Harrison Cripps as senior surgeon, the matron, and the clerk. Their Royal Highnesses were conducted to the waiting hall of the new building where the band of the Honourable Artillery Company, which corps also furnished the guard of honour, was in attendance. Here, among others, were assembled the Lord Mayor of London and the Sheriffs, Sir R. Douglas Powell (President of the Royal College of Physicians of London), Sir J. C. Dimsdale, Alderman Sir Thomas Boor Crosby, the members of the medical and surgical staff, and Dr. T. W. Shore, dean of the Medical School.

Lord LUDLOW then addressed the Prince, pointing out how in 1324 Edward II., who before ascending the throne had been the first Prince of Wales, had confirmed the hospital in its property and privileges. The foundation-stone of the present buildings had been laid by His Majesty the King on July 6th, 1904. By the provision of these buildings not only would the out-patients be able to be treated more satisfactorily but also the junior officers of the hospital, the house physicians and surgeons who were in daily and nightly attendance on the patients, would be housed in a satisfactory manner. The treasurer concluded by asking his Royal Highness to declare the building open.

The PRINCE OF WALES, in reply, said: "As President of this ancient and celebrated hospital I have much pleasure in taking part in the ceremony of opening these new buildings, the foundation-stone of which was laid three years ago by the King, and I am glad that the Princess of Wales has accompanied me on what is an important occasion in the history of this institution. It is interesting to note how from the earliest days the British Sovereigns or their families have been personally associated with St. Bartholomew's, and I am proud to think that the presidency so long held by my father should have been continued in me after his accession to the Throne. We have good reason to congratulate ourselves upon the achievement which, thanks to the generous support of the public, we are able to inaugurate to-day, for the building will add greatly to the efficiency of the hospital and will afford the most perfect methods of observation and treatment for out-patients, and will at the same time provide suitable accommodation for those members of the medical staff who by day and night are in attendance on the patients. Better accommodation for the nurses still remains to be provided, and I wish all success to the fund for the erection of a nurses' home which has been started by Lady Ludlow, the wife of our treasurer. I trust that at no distant date this important addition may be carried out. The Princess and I sincerely thank you and all those who work for the well-being of the patients of this ancient and charitable foundation for the kindly sentiments to which your address gives expression, and I have now much pleasure in declaring this building open."

Mr. E. B. I'Anson, F.R.I.B.A., the architect of the new buildings, was presented to their Royal Highnesses and the ceremony of opening terminated.

The Princess of Wales had been elected as a governor of the hospital on June 27th, and the treasurer now asked Her Royal Highness if it were her pleasure to receive her charge. Her Royal Highness having expressed her willingness, the Clerk read the charge as follows:—

> May it please your Royal Highness,—Your Royal Highness having been elected and chosen a governor of St. Bartholomew's Hospital, it is your duty and charge to acquit yourself in that office with all faithfulness and sincerity, endeavouring that the affairs and business of the said hospital may be well ordered and managed, and promoting the weal and advantage of the poor wounded, sick, maimed, diseased persons harboured in the said hospital. To this end your Royal Highness is now admitted a governor of St. Bartholomew's Hospital.

The Prince and Princess of Wales inspected the new buildings, a short description of which was given in THE LANCET of July 9th, 1904, on the occasion of the laying of the foundation-stone, and after visiting *Mark* and *President* wards in the old buildings they left the hospital.

PATENT MEDICINE DUTIES AND INFORMERS.

To the Editor of THE LANCET.

SIR,—In accordance with the promise I gave you in my last, I now proceed to make a few observations on the "Medicine Stamp Act."

When an informer lays an information, the worthy clerks of the Stamp Office question him as to his name and address, but in a manner which, it is at once convincing enough to the hearer, there is little occasion for. When they make out a "good case," the plan pursued is, to summon the offender to the Court of Exchequer, on such a day, where he is to attend with his solicitor to defend the action, viz., "the Attorney General *versus* Yourself, under a fine of £100." This, Sir, is the puffing summons sent by the Solicitor of Stamps; puffing it may well be called, for it is never put into effect; it acts merely as an organ of terror to the affrighted defendant. Thus do these precious worthies bully and bluster. The defendant, thinking it would be madness to defend an action where the Attorney General is plaintiff, petitions the Commissioners of Stamps for a mitigation of the penalty, (£10), which he almost invariably obtains, to £4.

The following are some of the articles which must bear a stamp:—

1. All patent medicines, numbering 553;* and the apothecary may not sell any small quantity (though not of the original article) under the patent name, without a stamp.

2. No article must be vended to which is prefixed a label describing it to be a specific for any disease, provided the person so vending pretends to any secret science of preparing the same.

3. All lozenges sold with an intent to relieve pain, or remove any malady, excepting ginger and peppermint lozenges; but not those if they are recommended as specifics. All other articles of confectionary may be sold.

4. "The water clause."—Soda, Seidlitz water, and powders,

as is consistent with their perforative power, for were they cut very obliquely it might happen that in some cases, when inserted through the membranes of the spinal canal, part of the aperture was in the subarachnoid space and part outside. Consequently, when the solution was injected analgesia would be absent or imperfect. The needle-holder consists of a hollow tube into which a removable handle, set obliquely, is screwed; one end fits into the socket of the needle, the other admits the nozzle of the syringe and has a stopcock interposed for shutting off the flow of cerebro-spinal fluid when required. The syringe has an improved glass barrel of ten cubic centimetres capacity, to which is adapted a very accurately fitting solid metal plunger, the nickel-plated metal mounts being soldered on to the glass barrel. There are no leather or other washers to get out of order. The puncture knife, which is diamond shaped, is used for penetrating the skin after it has been frozen with the spray of ethyl chloride. By this means two objects are attained: (1) it renders the procedure more aseptic, as the needle is not likely to become contaminated with micro-organisms from the skin; and (2) it prevents the point of the needle from becoming blunt by its passage through frozen tissues. The whole apparatus can be readily sterilised, but care must be taken first to place the apparatus in cold water, which is gradually boiled, otherwise the glass barrel of the syringe is liable to crack. E. CANNY RYALL, F.R.C.S. Irel.

Harley street, W.

NEW SYDENHAM SOCIETY: A STRUGGLE FOR EXISTENCE.

THE following report will be made public at Exeter on Thursday, August 1st, and will not, we think, constitute very pleasant reading for those members of the medical profession who know the valuable work done by the society:—

REPORT.

The works issued during the year 1906 consisted of two double fasciculi of the Clinical Atlas illustrating the subjects of variola, vaccinia, and varicella, and of a printed volume containing selected papers on the Parasites of Syphilis and Small-pox. For the current year a double fasciculus is already in the hands of the members and a second double fasciculus devoted to gynæcological subjects is almost ready for issue. The fasciculi of the Atlas, though fewer in number, are illustrated at greater cost than usual, since almost the whole of the plates are coloured. The treasurer's accounts have been audited and show that at the end of the year (December, 1906) there was a balance of £124 2*s*. 1*d*. but as two cheques amounting to £91 6*s*. had not been presented for payment the real balance amounted to £32 16*s*. 1*d*. Against this, however, were to be set off certain liabilities chiefly for work in progress. Part of this has since been discharged and the secretaries are of opinion that at the close of the present year it is not likely that more than £250 will remain due.

For several years past the treasurer and council have been unable to contemplate without some misgiving the financial position of the society. Too sanguine expectations were entertained during the first years of the issue of the Clinical Atlas and these led not only to the printing of an edition much larger than has been required but to a more liberal expenditure on plates and letterpress than could be afforded. It was anticipated that there would be a larger demand for the back fasciculi than has been realised. The nature of this work rendered it inevitable that the arrangements should be made well beforehand and obligations undertaken. The result was that for several years past the annual income has been to some extent burdened by debts incurred in former years as well as by some which were prospective. It was impossible to allot to each year its own share in expenditure and the auditors were repeatedly obliged to note that whilst the income and outgoings were balanced there remained some outstanding accounts with artists, &c. By careful management during the last two or three years this state of affairs has in part been rectified. No liabilities which could possibly be avoided have been incurred; the edition sent to press has been reduced, advertisements have been almost wholly stopped, the society's agent has accepted a smaller salary, and in every direction the strictest economy has been enforced. If the society were to cease receiving subscriptions at the end of the current year it would be free from engagements beyond the above-mentioned indebtedness of £250, which the realisation of its stock in hand should suffice to discharge.

At a meeting of the council held in December, 1906, when the above facts were fully discussed, a resolution was passed to the effect that it was desirable to submit to the annual meeting a proposal that the society should wind up its affairs. It was felt and expressed by several members of the council that the society had to a large extent completed its vocation. The activity of medical publishers of the present day is wholly different from that which prevailed when the society was instituted half a century ago. Publication under the auspices of a council, bound by rules which entail delay, and controlling only a limited annual income, cannot now compete with the energy and promptitude of individuals who are free to exert their own untrammelled judgment and to act promptly. The works left for the society's selection are now for the most part only those for which the publishers do not think there would be much demand; this applies especially to large printed books, but to some extent also to pictorial illustrations. For the production of the latter new and improved processes are constantly being produced of which a society having a work in current issue and unable to encounter pecuniary risk cannot well avail itself.

Six months have passed since the resolution just referred to was adopted and nothing during that time has transpired to induce those who know most about the details to change their views. For several years the loss of members by death or resignation has been in excess of its gains, and it is obvious that if, under closer financial pressure, the annual issue of books should be reduced the resignations would be likely to increase. It may seem to some almost a defect in courage or energy to contemplate the winding up of a society which yet numbers over 900 members and enjoys a corresponding income. It is true that such an income would suffice for a respectable annual issue of medical literature. The society at the present appears, however, to have no aims before it sufficiently definite and attractive to prevent further dwindling. The Atlas in its present form requires for success a very large income. It has been planned on too large a scale, and in endeavouring to meet the requirements of all it has disappointed many. It is clear that it must be either much modified or be discontinued. Nor does the council feel that there are any works suitable for translation the publication of which would be acceptable and likely to revive the society's former prosperity. In the circumstances which have been explained the society has determined to submit to the judgment of the annual meeting the subjoined proposals:—

1. That the society be continued on the understanding that the council will restrict itself to certain defined objects as follows: in the first place, the issue of an annual volume consisting of short monographs or essays carefully selected and translated promptly after their original publication; and in the second place, of one or more fasciculi of the Atlas, which should concern themselves chiefly with illustrations of the subjects dealt with in the printed volume or of those exhibited in the annual museum of the British Medical Association. Each fasciculus to be complete in itself.
2. That the society be continued, but its work be restricted to the translation and publication for series of foreign monographs or essays, the production of the Atlas or of expensive illustrations in any form being discontinued.
3. That the society be continued, its scope being left as heretofore to the judgment of the council for the time being.
4. That the society shall not be continued beyond the end of the current year. That the present officers be requested to be good enough to remain in office in order to wind up its affairs and be empowered to deal as may be thought best with the stock in hand and with any profits that may accrue from its sale.

At a large and influential meeting of the council held in London on July 18th it was decided to recommend the adoption of proposal No. 4 to the annual meeting, but it was also decided that in the event of this proposal not meeting with approval the alternative proposals 1, 2, and 3 be put before the members.

INTERNATIONAL CONGRESS AGAINST ALCOHOLISM.—The president and the honorary secretary (*pro tem.*) of the National Temperance League have communicated to the *Times* a resolution recently arrived at by prominent British representatives of temperance organisations to invite this congress to meet in London in the year 1909. The Duke of Connaught has consented to act as honorary president of the congress in the event of the invitation being accepted, and among those who have agreed to act as vice-presidents are the Archbishop of Canterbury, Lord Alverstone, Lord Kinnaird, Mr. John Burns, Sir George Livesey, Sir Victor Horsley, and Professor G. Sims Woodhead.

for whilst the mortality from this disease in the urban districts of England averages 1483 per 1,000,000 it does not exceed 849 per 1,000,000 in the rural districts. The disease is everywhere more fatal to the male sex than to the female. As a means of tracing the relation of season to pneumonia fatality the official records for extra-metropolitan England afford no assistance, but the method adopted by the Registrar-General of publishing weekly returns for London offers exceptional facilities for this purpose. Taking the average of the last five years, it appears that in the metropolis 62 per cent. of the deaths from this disease occur in the first and last quarters of the year, taken together, whilst in the remaining half of the year the proportion does not exceed 38 per cent. Another condition of great importance from a public health point of view is that which is known as "puerperal fever," a name disapproved by the Royal College of Physicians—the proper designation being "puerperal septicæmia" or "puerperal pyæmia." The mortality from puerperal fever and other accidents of childbirth has not varied greatly in the course of the last 40 years. In the decennium recently closed the rate was equal to 295 per 1,000,000 of the female population at all ages, married and unmarried together. Expressed in terms of registered births, the ratios in the last four decennia have been 4·69, 4·75, 4·73, and 5·09 per 1000 severally. The mortality was therefore somewhat higher in the recent ten-year period than in any of its three predecessors. This increase, however, is almost certainly due partly to improved certification and partly to the system of inquiry before referred to.

The report before us contains highly interesting references to the behaviour in recent years of certain other prevalent and very destructive diseases; more especially to the several forms of tuberculosis, to cancer, and to the vastly important subject of infantile mortality. In the present article no space remains for adequate notice of these subjects, but we hope to return to their consideration on a future occasion.

THE NEW BUILDINGS OF ST. BARTHOLOMEW'S HOSPITAL.

ON July 23rd His Royal Highness the Prince of Wales opened the new departments for out-patients at St. Bartholomew's Hospital. The Prince, who is President of the hospital, was accompanied by the Princess and on arrival at the hospital at about 3.30 P.M. was received in the Great Hall by Lord Ludlow (the treasurer), the almoners, Dr. Norman Moore as senior physician, Mr. Harrison Cripps as senior surgeon, the matron, and the clerk. Their Royal Highnesses were conducted to the waiting hall of the new building where the band of the Honourable Artillery Company, which corps also furnished the guard of honour, was in attendance. Here, among others, were assembled the Lord Mayor of London and the Sheriffs, Sir R. Douglas Powell (President of the Royal College of Physicians of London), Sir J. C. Dimsdale, Alderman Sir Thomas Boor Crosby, the members of the medical and surgical staff, and Dr. T. W. Shore, dean of the Medical School.

Lord LUDLOW then addressed the Prince, pointing out how in 1324 Edward II., who before ascending the throne had been the first Prince of Wales, had confirmed the hospital in its property and privileges. The foundation-stone of the present buildings had been laid by His Majesty the King on July 6th, 1904. By the provision of these buildings not only would the out-patients be able to be treated more satisfactorily but also the junior officers of the hospital, the house physicians and surgeons who were in daily and nightly attendance on the patients, would be housed in a satisfactory manner. The treasurer concluded by asking his Royal Highness to declare the building open.

The PRINCE OF WALES, in reply, said: "As President of this ancient and celebrated hospital I have much pleasure in taking part in the ceremony of opening these new buildings, the foundation-stone of which was laid three years ago by the King, and I am glad that the Princess of Wales has accompanied me on what is an important occasion in the history of this institution. It is interesting to note how from the earliest days the British Sovereigns or their families have been personally associated with St. Bartholomew's, and I am proud to think that the presidency so long held by my father should have been continued in me after his accession to the Throne. We have good reason to congratulate ourselves upon the achievement which, thanks to the generous support of the public, we are able to inaugurate to-day, for the building will add greatly to the efficiency of the hospital and will afford the most perfect methods of observation and treatment for out-patients, and will at the same time provide suitable accommodation for those members of the medical staff who by day and night are in attendance on the patients. Better accommodation for the nurses still remains to be provided, and I wish all success to the fund for the erection of a nurses' home which has been started by Lady Ludlow, the wife of our treasurer. I trust that at no distant date this important addition may be carried out. The Princess and I sincerely thank you and all those who work for the well-being of the patients of this ancient and charitable foundation for the kindly sentiments to which your address gives expression, and I have now much pleasure in declaring this building open."

Mr. E. B. I'Anson, F.R.I.B.A., the architect of the new buildings, was presented to their Royal Highnesses and the ceremony of opening terminated.

The Princess of Wales had been elected as a governor of the hospital on June 27th, and the treasurer now asked Her Royal Highness if it were her pleasure to receive her charge. Her Royal Highness having expressed her willingness, the Clerk read the charge as follows:—

> May it please your Royal Highness,—Your Royal Highness having been elected and chosen a governor of St. Bartholomew's Hospital, it is your duty and charge to acquit yourself in that office with all faithfulness and sincerity, endeavouring that the affairs and business of the said hospital may be well ordered and managed, and promoting the weal and advantage of the poor wounded, sick, maimed, diseased persons harboured in the said hospital. To this end your Royal Highness is now admitted a governor of St. Bartholomew's Hospital.

The Prince and Princess of Wales inspected the new buildings, a short description of which was given in THE LANCET of July 9th, 1904, on the occasion of the laying of the foundation-stone, and after visiting Mark and President wards in the old buildings they left the hospital.

PATENT MEDICINE DUTIES AND INFORMERS.

To the Editor of THE LANCET.

SIR,—In accordance with the promise I gave you in my last, I now proceed to make a few observations on the "Medicine Stamp Act."

When an informer lays an information, the worthy clerks of the Stamp Office question him as to his name and address, but in a manner which, it is at once convincing enough to the hearer, there is little occasion for. When they make out a "good case," the plan pursued is, to summon the offender to the Court of Exchequer, on such a day, where he is to attend with his solicitor to defend the action, viz., "the Attorney General *versus* Yourself, under a fine of £100." This, Sir, is the puffing summons sent by the Solicitor of Stamps; puffing it may well be called, for it is never put into effect; it acts merely as an organ of terror to the affrighted defendant. Thus do these precious worthies bully and bluster. The defendant, thinking it would be madness to defend an action where the Attorney General is plaintiff, petitions the Commissioners of Stamps for a mitigation of the penalty, (£10), which he almost invariably obtains, to £4.

The following are some of the articles which must bear a stamp:—

1. All patent medicines, numbering 553;* and the apothecary may not sell any small quantity (though not of the original article) under the patent name, without a stamp.

2. No article must be vended to which is prefixed a label describing it to be a specific for any disease, provided the person so vending pretends to any secret science of preparing the same.

3. All lozenges sold with an intent to relieve pain, or remove any malady, excepting ginger and peppermint lozenges; but not those if they are recommended as specifics. All other articles of confectionary may be sold.

4. "The water clause."—Soda, Seidlitz water, and powders,

directed to very minor ailments has been attempted by the education authority, as it is very generally agreed that "to treat the ailment discovered would tend to pauperise the parent." The Committee on Physical Deterioration thought that "in no instance should the inspector do more than state the facts that require the attention of the parent, cases of poverty and neglect being left to the proper authorities to deal with." The Committee on Medical Inspection expressed the opinion that if the children were treated as well as examined the cost would be very materially increased and that medical practitioners would have ground for complaint, more especially in those numerous instances where the school medical officer would also be in private practice. For our part, we agree that the education authority should content itself with informing the parents of the actual conditions observed, leaving them to arrange for treatment in the usual fashion. It is by this means that the cordial coöperation of the medical profession throughout the country will be best insured and that the maximum benefit from the medical inspection of children is likely to result. The medical profession itself has a delicate task before it in so far as the actual inspection of the school children is concerned, but we feel sure that the high ideals which have always animated professional conduct will enable whatever reasonable project is devised to be carried out in the interests of the children.

◆

The Duties of Certifying Surgeons under the Workmen's Compensation Act, 1906.

ON another page a letter is published from a certifying surgeon under the Factory and Workshop Act, 1901, who has received from the Home Office documents designed to supply him with information as to the fresh duties assigned to him and to those holding similar appointments by the Workmen's Compensation Act, 1906. The last-named statute has probably attracted more general attention than any recent piece of domestic legislation, not even excluding the Education Act passed by the late Government, owing to the inclusion of the enormous class of domestic servants in its provisions, a class not likely to have recourse with any great frequency to its assistance. Innovations of more genuine importance to those sought to be benefited and to those charged with carrying the new law into effect are those which assign compensation for personal disablement to workers who have always been liable to be disabled, either through their own fault or the neglect of their employers, or perhaps from a combination of the two causes, but who hitherto have had to accept the risks of their employment and to bear unaided any resultant injuries. The inclusion of industrial diseases and the incapacity arising from them, so that these are reckoned as if they were personal injuries by accident arising out of, and in the course of, the workman's employment, adds to the duty of the employer to protect his workman by guarding against any such disease the liability to compensate him if, in spite of or in the absence of precautions, he should contract it. The duty of investigating the alleged occurrence of industrial disease has been assigned to medical men specially appointed under the Factory and Workshop Act, 1901, and known as certifying surgeons, chiefly on account of the certificates which they are called upon to grant as the result of the medical examination of juvenile candidates for employment. These gentlemen receive notice of all accidents of a specified character in factories and workshops and of the occurrence of certain industrial diseases mentioned in the Factory and Workshop Act, 1901, to which the Home Secretary has power to add by Special Order, and it is their duty to investigate such cases and to report upon them. Not unnaturally, therefore, in order to secure accurate evidence in connexion with the industrial diseases which are to rank as accidents under the Workmen's Compensation Act, 1906, fresh duties have been imposed upon the certifying surgeons on account of the position which they already occupy and of their familiarity with the subjects to be dealt with. The defining of the procedure to be adopted under the new Act has involved a certain amount of reference to that already prescribed by the Factory and Workshop Act, and the combination of two statutes with their accompanying regulations is likely to afford to certifying surgeons a certain amount of subject matter for careful study.

We do not anticipate that as the result of such study the fears expressed by our correspondent already alluded to will be found to be justified, or that the duties which add new importance to the responsible post of certifying surgeon are as wholly unrewarded as they would be if the personal examination, followed by certification, of a man suffering from a possibly obscure and complicated disease were to entitle the medical man to a fee of 1s. only. The circular to which our correspondent refers dwells, it is true, on the necessity for care in filling up the required certificate, the fee for which is in certain circumstances 1s. Reference, however, to the regulations which accompany the circular shows that when the fee is limited to 1s. it is for the giving of a certificate only, the material for which has been obtained through an examination paid for as such. The fee, in short, is fixed at 1s. where the medical examination of the workman has to be made by the certifying surgeon under the Factory and Workshop Act, 1901, or under the special rules or regulations of the Home Office for the carrying out of that Act. The rule which relates to cases not under the Factory and Workshop Act provides "in all other cases a fee of 5s., and where the workman is unable to present himself for examination at the residence of, or other nearer place fixed by the certifying surgeon, for every mile or portion thereof which the certifying surgeon is required to travel therefrom for the purpose of examining the workmen an additional fee of 1s." These are fees to be paid by a workman seeking to establish that he is suffering from a disease contracted in such circumstances as to render him a subject for compensation. There is provision under the Act and under the rules made by the Home Secretary to meet the case of an employer who may seek for a certificate that the disease contracted by the workman is not due to the nature of the employment so as to render his master liable; for this certificate the fee is fixed at 2s. 6d., but presumably such a certificate will only be wanted when a workman has already been examined and the examination paid for by him in the endeavour to establish the liability of the employer.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: O. W. Andrews to the *President*, additional, for Deptford Victualling Yard, temporary; J. A. Moon to the *Prince of Wales*; W. G. Axford to the *Magnificent*; H. W. A. Burke to the *Wildfire* and for Sheerness yard; and J. Menary to the *President*, additional, for three months at West London Hospital. Surgeons: S. F. Dudley to the *Queen*; O. Mills to the *Donegal*; and N. H. Harris to the *Defiance*.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon Thomas Edward Henry Williams has been placed on the Retired List at his own request, with permission to assume the rank of retired Deputy Inspector-General of Hospitals and Fleets (dated July 12th, 1907).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Edwin O. Milward is placed on retired pay (dated July 24th, 1907).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Henry G. Smeeth to be Surgeon-Captain (dated July 6th, 1907).

IMPERIAL YEOMANRY.

Lancashire Hussars: Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel D. Harrisson to be Surgeon-Lieutenant-Colonel (dated June 9th, 1906), and to be granted the honorary rank of Surgeon-Colonel (dated June 20th, 1907). Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel D. Harrisson resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated June 21st, 1907). Lincolnshire: Robert Black Purves (late Surgeon-Captain, 1st Edinburgh (City) Royal Garrison Artillery (Volunteers)), to be Surgeon-Lieutenant (extra) (dated May 14th, 1907).

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion, the Manchester Regiment: Surgeon-Major George Henry Darwin, retired, to be Surgeon-Major (dated Oct. 30th, 1906).

THE FATHER OF KAID SIR HARRY MACLEAN.

The following interesting paragraph is taken from the *Army and Navy Gazette* of July 20th: "Those who knew Deputy Inspector-General Andrew Maclean in the days when he did duty as a medical officer on the staff of the army will be glad to learn that the veteran soldier has recovered from his illness and is in as good a state of health as can be expected having regard to his advanced age—he has reached his ninety-fifth year. He is father of Kaid Sir Harry Maclean, whose captivity has naturally occasioned him anxiety. Dr. Maclean lives in the neighbourhood of Kew Gardens, and was until recently to be seen taking his daily walk with little outward evidence of age or infirmity."

Correspondence.

"Audi alteram partem."

EXPERIMENTS ON PROLONGED PROTEIN FEEDING.

To the Editors of THE LANCET.

SIRS,—In a very interesting and instructive paper on the above subject, published in THE LANCET of July 20th, Dr. David Forsyth has discussed at some length some views which I have recently advanced as to the relationship of diet to the thyroid gland, based on the results of an experimental investigation into the effects of an excessive meat diet in animals. As I think that Dr. Forsyth has unwittingly given an erroneous impression of the results recorded in my paper and of my interpretation of them, I would like with your permission to offer a few very brief comments on his paper.

Dr. Forsyth is, I think, hardly correct in stating that he has repeated my observations. His experiments differed from mine in two important particulars. My experiments were directed to ascertain the effects of an exclusive meat dietary and the food was given in an uncooked condition in order that all the nutritive juices and soluble salts of the meat should be consumed by the animals. In his experiments Dr. Forsyth supplemented the meat diet by the addition of inorganic salts and possibly other foodstuffs, and the meat was cooked, the water used in the cooking not being utilised for the feeding of his animals. At the meeting of the Physiological Society in November, 1905, at which the fowls fed by Dr. Forsyth were exhibited, I was much struck by the difference in the dietetic conditions in his observations and mine.

With regard to Dr. Forsyth's interpretation of the changes in the thyroid and parathyroid glands recorded by me, I fear that his presentation of my results and my interpretation of them has been unconsciously coloured by his desire to harmonise my results with his theories. The possible fallacies suggested by Dr. Forsyth were not unknown to me, and I am satisfied that they do not affect the results. It is true, as Dr. Forsyth points out, that the weights of the glands recorded in my paper are not as complete as they should have been. This is accounted for by the fact that my research was primarily an experimental investigation into the nature of avian gout and the changes in the thyroid and parathyroid glands were, so to speak, an accidental finding, and two out of the three greatly enlarged glands were partially utilised for sections before the probable significance of the enlargement was appreciated. Since the thyroid glands in all three fowls were at least eight times larger and heavier than the glands of a control animal of similar weight, and as this condition was associated with an equally striking enlargement of the parathyroid glands, it did not seem to be possible to arrive at any other conclusion than that arrived at, and I am still of this opinion.

In his paper Dr. Forsyth suggests that the possibility of a deficiency in inorganic material in a meat diet being an important factor in such experiments was first brought to my notice when my paper was discussed at a meeting of the Pathological Society of London. This is not the case. My original investigation was undertaken in order to confirm or otherwise the results of an interesting series of experiments by Kionka on avian gout induced by meat feeding, which were published in 1900, and are referred to in my original paper. In his writings Kionka not only makes a special reference to the deficiency of lime in a meat diet but his main paper is followed immediately in the same journal by a second communication dealing exclusively with the influence of lime in his experiments. In my later feeding experiments with rats referred to by Dr. Forsyth my object was to repeat as closely as possible the dietetic conditions obtaining in my earlier observations. I have elsewhere pointed out that the consideration of the ultimate causes of the structural changes observed—whether due to excess or deficiency of particular foodstuffs in a meat diet—was beyond the scope of my recent communications.

May I, in conclusion, offer one comment on the very interesting facts recorded by Dr. Forsyth in that section of his paper dealing with the structure of the thyroid gland in birds of prey. I was specially interested in the five different types of glands which are shown in his illustrations, as characteristic of the eagle, ostrich, falcon, &c., but I have doubts as to the validity of the conclusions he draws from them. An extensive experience of the histology of the thyroid gland of animals under different conditions leads me to think that more than one of the five appearances illustrated are pathological and are the results of the disturbed state of general nutrition which has led to the tissue being available for examination by Dr. Forsyth. I am strengthened in this view by the fact that I can show, from some unpublished data on the thyroid gland of experimentally-fed cats, appearances apparently identical with those described by Dr. Forsyth in the five different species of birds, the appearances in my sections being obtained under conditions which leave no room for doubt, in my mind at any rate, as to their having an important etiological relationship to dietetic conditions.

I am, Sirs, yours faithfully,
CHALMERS WATSON.

ATHLETIC CHAMPIONSHIPS AND NATIONAL PHYSICAL DEVELOPMENT.

To the Editors of THE LANCET.

SIRS,—In your leading article on the above subject you refer to "the winning of the Grand Challenge Cup at Henley for the second year in succession by a Belgian crew, the recent victories of colonial football players, the success of M. Massey at golf, of Mr. Gould at tennis, and of Mr. Brookes at lawn tennis"; and you express a doubt as to have abundant opportunities of studying carefully malignant disease how much greater is it with those who are untrained? With many "cancer curers" any swelling is a cancer, and even with those who have no motive for miscalling a simple growth or an inflammatory swelling the word cancer is used with a freedom unjustified by the course of the disease. When, therefore, a new remedy that is claimed to be a remedy for cancer is introduced there is a natural feeling of doubt that the introducers of it have been hasty in bringing it forward, and not until it has been tested and re-tested can it be admitted as a trustworthy treatment.

One of the recent cancer "cures" that has received more public notice than is usually accorded to new remedies is trypsin. The history of its introduction is of itself interesting. In 1902 Mr. J. BEARD, a Doctor of Science of Victoria University and University lecturer in comparative embryology, Edinburgh, first propounded the theory that malignant growths are nothing more than the result of the development of vagrant irresponsible germ cells. This theory must not be confused with COHNHEIM'S suggestion that tumours may develop from embryonic "rests," for these would consist of somatic cells. Dr. BEARD further maintains that the majority of unutilised germ cells or trophoblasts are destroyed in the normal development of an embryo about the time that the pancreas commences its functional activities. He holds that the trophoblast nourishes itself by an acid intracellular digestion and that when the stronger alkaline enzyme of the pancreas appears on the scene it is able to overcome the intracellular enzyme of the trophoblast and therefore brings to an end the growth of the trophoblast. The deduction from these *theories* jumps to the eyes. If in the normal development of the body the trophoblasts are destroyed by the pancreatic ferments, and if cancer is only the result of the persistence of a trophoblast, then the introduction of pancreatic ferments should lead to the destruction of the cancer. Each of these "ifs" is rather large, but granting the premisses we can hardly refuse the conclusion. It is, to say the least, curious that the utilisation of pancreatic ferments should have suggested itself to other observers and for entirely different *reasons*. There is an excess of glycogen in the active cells of carcinomata, as in all rapidly growing tissue. Dr. J. A. SHAW-MACKENZIE has suggested that this excess of glycogen in cancers is due to insufficiency of the pancreas and naturally he came to the conclusion that it would be well to try the action of pancreatic ferments in malignant disease. Similarly Dr. R. ODIER of Geneva has advised a mixture of the extracts of the pancreas, the liver, and muscle in the treatment of cancer. So far theory only has spoken but Dr. BEARD proceeded to test his theory by the injection of trypsin into some mice which had been inoculated with Jensen's mouse tumour. Two were inoculated and others were kept as controls. Of the two inoculated mice, one died from an accident ten days after the commencement of the injections and its tumour was only half as large as those in the controls, while the second inoculated mouse was killed after three weeks' treatment and the tumour was very much reduced in size; in both the injected cases there was a uniform degeneration of all the cancer cells. It must not be forgotten that even in untreated cases of carcinoma very similar changes occur in the cells, and as to the diminution in size of the tumours some untreated cases of Jensen's tumour show as much decrease. With these observations we may reasonably compare those obtained by the Imperial Cancer Research Fund, in the annual report of which body the general superintendent states that trypsin has been carefully tested on mice with rapidly growing Jensen's tumours, that a large number of observations have been made, and that it has been proved that the treatment "is incapable of curing mice of inoculated cancer or of influencing the progressive growth of tumours."

We come now to consider the employment of the treatment in human beings. Many failures have been met with but we may mention that some of the unsuccessful cases appear to have been treated with solutions containing no trypsin, while sometimes the ferment has been destroyed by the employment of a syringe too soon after it has been sterilised by heat, but more recently these fallacies have been guarded against. Dr. C. O. RICE of New York reported in November, 1906, that he had treated four cases with trypsin; in three no marked change occurred, but in one, a case of laryngeal carcinoma, complete recovery resulted in two and a half months. Clinically it is said that there was no doubt as to the diagnosis but no microscopic examination was made. The cases which chiefly attracted attention in this country were those treated by Dr. W. J. MORTON of New York. He had 29 patients under trypsin treatment and public attention was drawn to these cases by articles in the London daily press. Depending only on a telegraphic summary of Dr. MORTON'S paper which appeared in the *Medical Record* of Dec. 8th, 1906, one or two newspapers published highly exciting articles on this "new cure for cancer." We are willing to concede to the authors and publishers of these articles a sincere desire to benefit suffering humanity; but their zeal was without discretion and their pathological knowledge superficial, and it is certain that many hopes were raised only to be dashed to the ground. If before these writers had entered on a campaign they had waited for fuller details they would have learned that the "cures" were more than doubtful. The most remarkable of Dr. MORTON'S cases was one with an extensive carcinoma of the breast It was said that a most remarkable atrophy of an entire cancerous breast had occurred, but when the fuller particulars arrived we learned in the first place that the tumour had been treated *not only* with injections of trypsin but also with x rays, and then the "fibrous mass" which remained was removed surgically. When a microscopic examination was made of the removed mass degeneration of the cancer cells with increase of connective tissue was found in the central part, but towards the edge the cells were evidently living and growing; in fact, the growth showed the typical appearance of scirrhous carcinoma. It will thus be seen that this case is worthless as any evidence of the curative power of trypsin. Of the remaining 28 cases treated by Dr. MORTON five have died under treatment, in five no change was apparent, and in 18 there was said to be some improvement. No further details have reached us on this point. Two of the patients with "epithelioma of the face" were said to be cured but we erroneously imagined that the Bill applied not merely to the sale of goods but to machinery and factories. A few days before this debate Denmark adopted the metric system for all purposes, so now England and Russia alone stand aloof in Europe.

All Southern and Central America have followed the example of Europe and the United States have commenced by making this system compulsory for electric measures, also in the medical department of the army, the navy, and public health. It is also obligatory for all purposes in Porto Rico and the Philippines.

Official reports show that this change has been wholly beneficial in the United States, even where civilians experienced only in the old system were hastily brought into the army and navy medical services during the recent war with Spain. The colonies have urged Great Britain to join them in the reform and will probably act alone, if necessary, as New Zealand has already legislated on the subject. As regards the medical services of the army and navy in this country Government could take immediate action without reference to Parliament and with the same advantages which followed in the United States. The result would probably encourage concerted voluntary action among medical men in civil life who might collect and record the names of adherents through a central committee. A commencement of metric practice might be delayed till a convenient percentage of names in any district or throughout the country were recorded.

I am, Sirs, yours faithfully,

July 22nd, 1907. T.

CERTIFYING SURGEONS AND THE WORKMEN'S COMPENSATION ACT, 1906.

To the Editors of THE LANCET.

SIRS,—Having just received from the Home Office documents respecting the duties and remuneration of certifying surgeons under the Workmen's Compensation Act, 1906, I shall be glad to know the opinion of certifying surgeons as to whether they consider the fees are such as should be accepted by self-respecting medical men and, if not, what steps can be taken in the matter. In the circular from the Home Office it points out that "the certificates are legal documents which will require great care in completion." I gather the fee for this legal document is *one shilling*, which includes a responsible and skilled examination, but the details are chiefly given in Section 8 and Sub-section 3 of the Workmen's Compensation Act, 1906.

I am, Sirs, yours faithfully,

July 16th, 1907. CERTIFYING SURGEON.

⁂ We comment upon the matter in another column.—ED. L.

POPLAR AND STEPNEY SICK ASYLUM DISTRICT.—The report of the managers of the Poplar and Stepney Sick Asylum District for the year ending Lady-day, 1907, shows that the total number of patients in the various asylums of the district at the close of the period with which the report deals was 926. In the Bromley asylum the patients from Poplar suffering from cancer of various regions numbered 44, while patients from Stepney suffering from the same disease numbered 20. During the year 18 nurses presented themselves for, and successfully passed, the examination in sick cookery in connexion with the cookery classes held under the auspices of the Technical Education Board of the London County Council. The medical superintendent reports that the first year's working of the new system under which case papers were substituted for the cumbrous system of medical relief books has been a great improvement upon the old method. Under an Order issued by the Local Government Board in 1905 the medical superintendent has the option of either having the case paper, upon which appear the diet, medicine, history, and all information regarding the patient, hung by the bedside, or else of having in addition to the case paper a bed card upon which is written by the nurse the diet prescribed for the patient, together with other useful information. The latter of these alternatives was chosen in the present instance and the results have proved very satisfactory. The case papers, which are kept under lock and key, have been specially useful in cases where patients previously treated present themselves for readmission.

THE IRISH INTERNATIONAL EXHIBITION.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Dublin, July 13th, 1907.

THOUGH the Dublin exhibition is called the Irish International Exhibition the international element is very small and unimportant. On the other hand, as Ireland is not a populous or industrial or wealthy country it naturally follows that the Irish exhibits are also somewhat poor. They are, nevertheless, interesting; they testify that efforts are being made and that these might be far more successful if the Irish could only receive a more business-like education and acquire greater technical knowledge. These considerations have a considerable bearing on the health and vitality of the race, particularly as such industrial efforts as have been made relate in the main to the production of food and of clothing. However, the most notable Irish industries have a building to themselves on one side of the grounds and it is the Central Palace that seems the most important and first attracts the visitor, if for no other reason than that it has been made the principal subject of the illustrated advertisements. Yet the middle of this building is a huge sort of meeting place and lounge where there are but few exhibits. The four wings, however, of this the main structure are well filled. Penetrating first the north wing I found a considerable amount of Irish and other furniture. The idea of sanitary furniture constructed for its own sake or specially for use in the hotels of the Touring Club and which was such an interesting feature at the Milan Exhibition last year has not yet travelled so far as Dublin. Nevertheless, as we more clearly understand the causes of the spread of disease something approximating to aseptic furniture will become more and more appreciated, especially in hotels and places frequented by a great variety of people. At several exhibitions I have noticed furniture of this description, but I found none at Dublin.

In the east wing there were a great display of whiskies and notably a huge pot-still belonging to the firm of John Power and Son which was established in Dublin in 1791. The statement made is that this whisky "is distilled in a pot-still from the wash derived from the fermented worts of home-grown malted and unmalted barley, with wheat and oats in small proportion." Close by, and as if suggesting an antidote, Augustine Thwaites has a model of the quaint little old house where in 1773 soda water was first made. In the window there is the old ledger opened at the page where the account was kept of the amount of soda water supplied to His Majesty George IV. Then again, likewise surrounded by other whisky exhibits, I found Wheatley's non-intoxicants, hop-bitters, &c. These were bottled and looked very much like ordinary ales. Here, also, were numerous tobacco exhibits, and tobacco is often as injurious, when smoked in excess, as beer, but this does not prevent many total abstainers from suffering the evil effects of tobacco.

In the south wing there were more tobaccos and more mineral waters, including the French Perrier water. Then there were meat preparations, such as Bovril soup and Brand's various delicacies and invalid foods. Levers' soaps, Price's patent candles, and Fry's chocolates came next, though it is difficult to see what connexion there can be between them. In the same wing Philip Harris and Co. of Dublin exhibit their scientific instruments, scales, thermometers, and electrical and chemical appliances of all sorts. As scientific exhibitors they would be quite isolated but for the proximity of John Clark and Co. of Dublin and Belfast who display surgical instruments, orthopædic appliances, hospital furniture, &c. As special to Ireland there are Irish linen bandages, the edges of which are woven so that they are very durable. The same firm has a high-pressure steam steriliser consisting of double copper cylinders and an outside jacket of Russian steel. It condenses its own steam and a pressure of from 15 to 40 pounds can be obtained according to the manner in which the safety valve is regulated. These are the only sterilisers made in Ireland and are becoming more and more an article of general use.

The west wing is mainly devoted to clothing. There are Killarney rugs and cloth made of pure wool, doubtless very warm and healthy to wear, but there is no clothing that professes to be sanitary clothing and even the non-inflammable flannelette, seen at almost all exhibitions, is not in evidence telephone box can scarcely be avoided. Many persons using the telephone speak needlessly near to the receiver. The message at the other end is no clearer for this and is often unintelligible in these circumstances. A message well delivered with words properly and concisely pronounced is faithfully recorded, even though it is spoken quite away from the receiver. The contamination of the receiver when it exists may therefore be avoided to a very great extent, but the air of the telephone call box is difficult to avoid and yet it must contain a whole menagerie of organisms, some of them without doubt pathogenic, and it should be the duty of the telephone authorities to protect their customers from the possibility of contracting disease in this way by providing for a constant renewal of the air and by keeping the station bacteriologically clean by the use of an efficient disinfectant.

BREAKFAST FOODS.

THE recent work of Professor Robert Harcourt on the food values of advertised "breakfast foods," which formed the subject of an annotation in our issue of May 4th, p. 1240, has been amply corroborated by the publication of the results of the analysis of 99 samples of various "breakfast foods" by Mr. J. G. A. Valin, in the laboratory of the Inland Revenue Department, Ottawa, Canada. Mr. Thomas Macfarlane, the chief chemist of that department, in issuing the report defines a "breakfast food" as consisting of a cereal which has been subjected to a certain amount of preparation or cooking, with or without the addition of some other food material. Determinations were made of the proteids, moisture, and fat. In a previous bulletin (No. 127) it was shown that rolled oats which have had no previous cooking never yield more than 3 per cent. of dextrin. Of the foods examined, only Beaver oats, Quaker oats, Saxon oats, and Pilson's oats appear to be made from oats, as judged by the percentage of fat present. The figures obtained by the analysis of rolled oats and of porridge made from the same afford a useful guide to the values of these foods. The figures are calculated on the dry substance :—

	Total proteids	Fat.	Sugars and soluble proteids.	Dextrin.	Starch.
Rolled oats	13·76	5·19	4·13	2·32	71·21
Porridge made without salt	18·72	0·55	0·34	7·62	67·41
" " with "	17·60	1·17	6·69	13·97	53·93

If the analyses of the four advertised varieties of prepared oats above mentioned are calculated on their dry substance the resulting figures show that they contain less than half the amount of dextrin present in porridge prepared by the old-fashioned way. The figures here recorded show that the method of cooking *oatmeal without salt* is a very ineffective way of predigesting the starch which it contains. Porridge cooked with salt contains twice as *much* soluble dextrin as porridge cooked without salt. Another fact which is brought out by these tests is that the fat seems to *disappear* during the cooking. It is possible that it may enter into some sort of combination with the proteids so as to render it incapable of removal by the usual solvents. It has been shown by Dr. Chamberlain of Washington that the fat of wheaten flour undergoes such a change in the process of baking bread. It is important to note that, calculating on the dry substance, bread contains from 13 to 16·76 per cent. of substances soluble in water after extraction by alcohol, representing an amount of dextrin far greater than that contained in most of the "breakfast foods" examined. It follows from this investigation that the claims as to "predigestion" made for advertised foods are often exaggerated. Porridge made with a suitable quantity of salt is vastly superior to most of them in this respect. As regards the processes of "rolling" and "flaking" the grains it is quite possible that the thinning out of the material increases the digestibility but it is questionable whether the advantage is worth the extra cost. "Breakfast foods" are usually sold in packages of varying weight, a fact which renders a strict comparison of prices impossible, but the price of these foods appears to vary from 5 to 23 cents per pound, whereas oatmeal or wheaten flour is retailed in Canada at from 3 to 4 cents per pound. In conclusion, reference may be made to the extravagant phraseology of the claims made for many of these foods. The language is similar to that employed by the manufacturers of quack medicine. We quote a few instances in illustration of this: "The natural food for creating power"; "Concentrated malted food; ready to eat. Pure, predigested, thoroughly cooked"; "A food for brain and nerve centres"; "Grain combined with vegetable or plant iron"; and "The natural food for creating power, repairing waste, maintaining energy."

CATS AS A PREVENTIVE OF PLAGUE.

SINCE Lieutenant-Colonel A. Buchanan, I.M.S., wrote in May last drawing attention to the value of the domestic cat as a preventive against plague and insisting on the fact that as the animal enjoys the unique distinction of being held sacred by Hindus and Mahomedans alike it would be difficult for even native suspicion to suggest sinister motives to Government in encouraging its breeding and maintenance, there have been several communications to the same effect in the Indian press the writers of which were apparently unaware that the subject had already been broached by Lieutenant-Colonel Buchanan. Writing to the *Pioneer* from Cherat on June 4th Major O. R. A. Julian, R.A.M.C., after deploring the want of success which has attended upon all efforts to deal with plague on scientific grounds, proposes that good healthy cats should be brought in small consignments and protected while breeding until they were sufficiently numerous for distribution. Then to encourage the natives prizes should be offered in each village, one for the finest cat and another for the best ratter. "I venture to think," continues Major Julian, "that the sporting or gambling instinct of the native would be appealed to and that he would probably turn up not only with his cat but with a bag of rats for the contest, and the extermination of rats would be an event of the near future and with them the plague." On June 15th Assistant-Surgeon S. M. Pavri wrote as follows to the *Times of India:* "The rat-flea-man theory being scientifically established, the desirability that every house should be without a rat is the burning question of the day. But so many and so varied are the religious superstitions and social prejudices among the peoples of India against this destruction of rats, and so wonderfully prolific is the rat itself, that how to achieve this end on the line of least resistance does, and I am afraid will, remain a moot point. ...... Under these circumstances may I venture to suggest a remedy which does not seem to have attracted the attention it deserves? I mean a rat-killing campaign by cats." Assistant-Surgeon Pavri then proceeds to argue that the getting rid of rats by means of their natural enemies is not calculated to arouse opposition or discontent on the part of "the sensible masses who will not reject the bargain when it is a question of life and death to them and their families." Under the head of "Notes and News" in the *Journal of Tropical Medicine and Hygiene* dated July 1st it is stated that "Lieutenant-Colonel Buchanan took a cat census of certain villages that enjoyed exceptional immunity from plague and of others that had been severely handled by the disease." The result showed that the immune communities harboured large numbers of cats, whereas in those that suffered the animals were scarce. Our contemporary is of opinion that "the expedient is one that is certainly worthy of attention, though it is difficult to see how the

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

DISTINCTION has recently been conferred upon two members of the University, the Principal, Sir Oliver Lodge, having received the honorary degree of D.Sc. of the University of Liverpool, and Professor Fiedler having been elected to the recently established professorship of German language and literature in the University of Oxford. As Professor Harvey Gibson pointed out, Sir Oliver Lodge was entitled to the highest distinction which the University of Liverpool could confer upon him, not only on account of the work which he previously did for University College but also on account of the distinguished position that he has made for himself as a leader in science. Fortunately Sir Oliver Lodge remains in Birmingham but in the case of Professor Fiedler, though we are glad that he has been appointed to so distinguished a position, we cannot help regretting that his appointment will make us the poorer by the loss of the example of his unremitting energy, his genial good fellowship, and his active sympathy and help in any work which required doing. During his tenure of office in Birmingham Professor Fiedler has not only advanced and extended his department but he has acted as chairman of the library committee and for some years he has been Dean of the Faculty of Arts. Oxford gains much by his appointment and Birmingham will not find it easy to replace a professor who has gained so great a hold both on the students and on the people of the city.

The Society of Chemical Industry.

The meeting of the Society of Chemical Industry recently held in Birmingham passed off very successfully. Fortunately the society came with the coming of the fine weather; consequently the excursions took place and garden parties were held under favourable conditions and the visitors saw Birmingham not quite at its best but in more favourable circumstances than had previously been experienced during this summer. At the general meeting, held in the medical theatre of the University, the Lord Mayor welcomed the visitors to Birmingham and the Principal, Sir Oliver Lodge, proffered the welcome of the University. Mr. Eustace Carey of Liverpool, the president of the society, delivered the presidential address, in the course of which he stated that the last 20 years had been a period of depression in the alkali trade and he attributed this to three causes: (1) the failure in giving and the failure in appreciating education; (2) the failure of the British patent law; and (3) the loss of markets due to the protection and tariffs adopted by old and important customers. With regard to education, however, he saw signs of improvement in this country in all grades and he had hopes with regard to the patent law which, it is hoped, will be passed in a short time. At the banquet of the society Sir Oliver Lodge pointed out that one of the things wanted in this country was an appreciation of university training by employers such as was said to exist in Germany, for without it the work of the universities in turning out well-equipped and well-trained men was comparatively useless. The last two days of the meeting were devoted partly to excursions to places of practical and scientific interest in the city and in adjacent parts of the country and partly to visits to the beauty spots of the neighbourhood. In the evening of the last day a garden party was held in the Botanical Gardens which were beautifully illuminated for the occasion. The guests were received by Professor and Mrs. Frankland, and were entertained with delightful music and by a magnificent display of fireworks.

Municipal Milk Depôts.

In its quarterly report the health committee states that after carefully considering the question in all its bearings the committee is unable to recommend the council to establish milk depôts. It points out that there is no satisfactory evidence that the establishment of such depôts has any appreciable effect on the infantile mortality, for the statistics which have been prepared to show that the infant death-rate is reduced by the utilisation of milk depôts are, it considers, open to objection and the good results which have been noted are possibly due to other causes.

Open Spaces.

In the first instance everything seemed to be going favourably with regard to the series of open spaces which the Birmingham Open Spaces Society desired the city to obtain and to maintain for its own general advantage. So far as the Black Patch is concerned Smethwick and Handsworth, in whose district it partly lies, are prepared to provide a considerable part of the purchase money, but they are not willing to undertake any responsibilities as to upkeep, and, of course, all the cost of the other sites at present available must fall upon the city. The whole matter was referred to the Baths and Parks Committee for a report as to cost and advisability, and the report is unfavourable. Without considering the cost of purchase, about which there would be little or no difficulty, the committee estimates that to put the Black Patch in proper order a sum of over £10,000 must be provided and the annual expenses would be about £1450. The cost of converting the other plots offered would amount to £1835 and the total capital cost including the balance of purchase money (£4000) and additional provisions which the committee suggests as desirable would be, in the committee's opinion, at least £15,950. In these circumstances the committee is of the opinion that the advantages to be gained do not justify the cost and it cannot recommend the council to accept the offers made. What the council will decide remains to be seen, but it may be pointed out that the committee's estimates of what it would be necessary to do, though perfectly justifiable and highly desirable, are possibly in excess of present requirements, and if it is a question of getting these spaces now or losing them for ever, it would surely be wise in the city's interests to secure spaces which are so necessary, to do nothing more to them than necessity compels at present, and to develop them as opportunity offers in the future. If they are secured as spaces they will be a valuable asset to the crowded areas and they can be retained as "lungs" for children, who can easily make themselves happy in the absence of all elaborate arrangements.

Presentation to Mr. W. F. Haslam.

For a period of 16 years Mr. Haslam acted as secretary of the Midland Medical Benevolent Society and the members, taking advantage of his recent resignation of the post, have presented him with a silver tea- and coffee-service, kettle, and rose bowl as a token of their very high appreciation of the excellent work which he has done for the society during his long term of office. Dr. W. P. Whitcombe, in making the presentation, referred to the devotion and labour which Mr. Haslam had given to the society and ascribed a large part of its success to his efforts.

The Health of the City.

The health committee reports that during the past half year the health of the city has been on the whole good and the records compare very favourably with those for the first two quarters in the preceding ten years. The birth-rate is rather lower than last year, 29·3 per 1000, as compared with 30 per 1000, and the death-rate was 17·9 per 1000, as compared with 16·9 during the same period of 1906, but had it not been for the severe and widespread attack of measles with which the city has been affected the death-rate would have been a record one for the first half of the year. There were more cases of typhoid fever than in the preceding year, but apparently they were due to the importation of contaminated shell-fish.

July 23rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Changes in the Medical Curriculum in the University of Edinburgh.

SOME time ago it was intimated in THE LANCET that an ordinance had been approved by the Senatus and the Court of the University of Edinburgh asking for alterations of an important nature in the medical curriculum. This ordinance, it was pointed out at the time, was opposed by some of the other Scottish Universities and was therefore likely to be blocked in its further course before the Privy Council and Parliament. The intimation which was received last week that the ordinance has been passed was a great and gratifying surprise. The new regulations will come into force in time a sterile toxin may be obtained by this method. Dr. Row concluded with an elaborate comparison between the properties of this salted toxin and those of Haffkine's plague prophylactic.

APEPSIA.

SINCE the late Dr. S. Fenwick in 1870[1] described the condition of atrophy of the stomach, a large number of observations have clearly demonstrated that in certain cases the chemical processes which normally occur in the stomach may be entirely abolished. Pathological observation has confirmed the view of Dr. Fenwick that this condition is the result of a more or less complete atrophy of the glands of the mucous membrane of the stomach. In addition to the name of "apepsie" which has been applied to the condition by French authors, it has been called "anadenia ventriculi" by Ewald, "phthisis ventriculi" by Georges Meyer, and "achylia gastrica" by Einhorn. An interesting and exhaustive monograph has been published on the subject by Dr. H. Français.[2] In his historical account he states that the term "apepsia" was introduced by Galen and used by Molière in his "Malade Imaginaire"; Rokitansky in 1843 refers to a stomach showing a marked condition of atrophy, but undoubtedly the credit of first recognising and describing the condition belongs to Dr. Fenwick. Ponfick, in 1873, and Quincke in 1876 described examples of gastric atrophy in association with pernicious anæmia. Apart from records of cases little advance was made from the publication of Dr. Fenwick's second paper in 1877[3] until Ewald in 1886 proved that hydrochloric acid was absent from the stomach in these cases. From that time onwards a large amount of work has been devoted to the chemistry of the gastric contents, among the most important being that of M. Hayem and his collaborators who have shown the importance of the organically combined chlorides in regard to gastric digestion and have investigated their quantity in this condition. Dr. Français comes to the conclusion that apepsia is not a pathological entity but a syndrome occurring in association with various morbid states, and characterised by the abolition of the digestive functions of the stomach. In the most advanced type examination of the gastric contents shows an entire absence of free hydrochloric acid and of organic combinations of that acid; in others there may be an absence of free acid but a certain amount of organically combined chlorine. In both groups the digestive power of the juice is found to be wanting as tested by its action on proteins. Dr. Français describes the condition of chronic apeptic gastritis as that with which apepsia is most frequently associated. This disease is much more common in women and may be a sequel of any chronic inflammatory process affecting the gastric mucous membrane. Alcoholism, lead poisoning, and excessive tobacco smoking are all regarded as possible causes, the last condition accounting for a considerable proportion of the cases in men. The pathological anatomy comprises various forms of inflammatory and degenerative changes in the mucous membrane, especially parenchymatous or glandular gastritis, interstitial or mixed forms of gastritis, mucous transformation, and complete atrophy. In the last condition, which is that which most forms tend to reach, the mucous membrane may have a thickness not greater than half a millimetre and may consist of little more than a low cylindrical epithelium on a foundation of connective tissue with a few short glandular tubes. Clinically there may be recognised a latent form in which the symptoms may be very slightly marked, a form associated with great pain either shortly after food or from an hour to two hours later, and a form associated with severe diarrhœa. A similar condition of apepsia is not infrequently seen in association with cancer, either of the stomach or other organs, with pernicious anæmia; and with certain infections and intoxications—such as typhoid fever, uræmia, and diabetes. Dr. Français, in collaboration with M. Lion, was able to produce experimentally a condition of apepsia in dogs by means of the injection of a gastro-cytolysine prepared from the rabbit, an observation throwing considerable light upon the production of the condition through infective fevers and intoxications. It is also maintained by some observers that apepsia may occur in association with chronic nerve diseases, such as tabes dorsalis, and with neuroses and neurasthenia. The diagnosis of the condition of apepsia is usually easy and depends upon the results of the examination of a test meal, but the differentiation of the condition giving rise to the apepsia, whether gastritis, cancer, pernicious anæmia, or other chronic disease, is often a matter of great difficulty necessitating a careful consideration of the history, symptoms, physical signs, and of the blood count. For treatment Dr. Français recommends a careful regulation of the diet, avoiding fatty foods, and giving lightly boiled eggs and meat in small quantity. He finds that kephir is most valuable in these cases, especially in those with diarrhœa, commencing with a diet of kephir only and gradually introducing other food substances. In cases of gastric cancer with pyloric obstruction kephir is, however, contra-indicated. M. Soupault has obtained good results in the cases with diarrhœa from the administration of dilute hydrochloric acid given with lemon juice in the form of lemonade during the meal.

THE HYGIENIC EFFICIENCY OF GAS FIRES.

AN elaborate series of practical observations on the use of gas fires for the warming of apartments will be found in a paper read by Mr. John H. Brearley of Longwood before the Institution of Gas Engineers and published in the *Engineer* of July 12th. Mr. Brearley considered that the best gas fire for warming a room was the one which gave the greatest proportion of radiation and the products from which were not allowed to enter the room. As sources of radiation he found that iron frets were superior to fire-clay "fuel" in the proportion of 136 to 125. Air-heating tubes or chambers at the back of a fire reduced the radiation. A thin body of "fuel" was essential to a high radiative efficiency. With regard to the loss of heat carried away with waste products (flue heat) Mr. Brearley said that it varied a great deal according to the method in which the fire was connected. The chimney should be allowed to draw a large portion of the air from the room without an excessive "vacuum" in the stove flue-pipe, as was the case when the whole of the air which left the room was drawn through the stove itself. For this reason those stoves which were provided with ventilating outlets, in addition to the flue-pipe, were to be commended. Where such devices were not used the whole of the chimney opening should never be blocked up. It was often assumed that the heating efficiency of a gas-fire stove was increased by doing this, whereas the reverse was the case. Tests that were made for carbon monoxide showed that this substance was either completely absent or else present in such small traces as to warrant the inference that gas fires did not produce carbon monoxide when properly constructed and kept clean. It was known that when a gas flame came into contact with a cold surface carbon monoxide was produced, but so far as gas fires were concerned this was almost entirely avoidable, and in cases of neglect it could only continue during the first few seconds after the fire was lighted. Flueless stoves should not be fixed in rooms which were habitually occupied as much carbonic gas escaped from them. These stoves were not so purification than had been obtained in the experimental works should be secured. Mr. R. Patterson, a Harbour Commissioner, said his experience of Belfast Lough, which he had known all his life, was that the whole of the banks opposite Holywood used to be covered by long crisp grass which was frequently washed, dried, and used for upholstering and packing purposes, being inoffensive. With the growth of Belfast and the gradual pollution of the lough with sewage this grass ceased to exist, its place being taken by the present foul-smelling ulva latissima. The latter was noticeable in 1870, in 1876 it became very objectionable, and it had gone on increasing steadily ever since. Mr. Redfern Kelly, engineer to the Harbour Commissioners, said there was a population by day of about 10,000 on the harbour estate. Of the two great shipyards the sewage from the one (Workman and Clark) was carted away and after having been dealt with was sold to farmers, while in the case of the other (Harland and Wolff) the sewage was discharged right into the tideway. The witness contended that the city corporation, being the health authority, was in a position to step in and to make the tenants of the Harbour Commissioners send their sewage out in the ordinary way. The blame, he said, was altogether with the health authority. In reply to the suggestion that if there was a nuisance on their property the Harbour Commissioners were the people to whom the health authority would naturally go in order to have it abated, Mr. Kelly said: How can we object to Harland and Wolff discharging into the tideway, seeing the corporation also discharges such immense quantities (sewage of about 370,000 people) into the tideway? Sir Otto Jaffe, in giving evidence, said that during the period typhoid fever had been prevalent in Belfast no single member of the Jewish community had been affected, and he attributed their immunity, among other reasons, to the fact that they abstained from eating shell-fish. Some further evidence having been given as to the laws regulating the use of shell-fish, Councillor James Gregg, M.R.C.V.S., gave evidence in regard to the milk-supply of the city and stated that the condition of the cowsheds and dairies, as a rule, was bad inside the city as regards the building of the cowsheds, their ventilation, the grooming of the cows, and the presence of tuberculous animals. He also thought that no pigs should be kept in the city. Mr James Dempsey, a former member of the corporation, in his evidence advised the amalgamation of the corporation, water, harbour, and Poor-law boards, and that they should act by committees. It also came out as a result of his evidence that at the workhouse 14,000 corpses were buried in a space of three and a quarter acres. Miss Jane Agnew, sanitary sub-officer, gave evidence as regards the conditions under which outwork was carried on in the city, and said that 255 houses which she had visited required to be cleansed and repaired. Mr. H. McManus, a member of the executive committee of the Belfast Trades' Council, said that in his opinion there was insufficient inspection in sanitary matters in Belfast. He advocated the preparation and public exhibition of maps showing the localities in which infectious disease was present so that people could keep away from them, and thus those possessing property would take more care in improving the hygienic and sanitary condition of it. Dr. J. Barron, Mr. S. B. Coates, and Dr. H. R Torrens, dispensary medical men, were next examined as to the state of their districts. Mr. H. Norman Barnett gave evidence to show that in a number of cases investigated by the Society for the Prevention of Cruelty to Children the cause of the horrible filth of the houses and their necessarily insanitary condition was not poverty (the inmates having wages of from £1 to £2 weekly) but that the wages were spent on strong drink, and so the mother was unable and unwilling to keep her house fit for habitation. Mr. J. S. Oswald (chairman of the Belfast board of guardians) said that the workhouse graveyard was well sewered, and all burials were made under the Public Health Act. His experience satisfied him that at the Abbey Sanatorium for Consumptives splendid work was being done. Dr. John McLiesh (visiting medical officer of the union infirmary) said that a great many of the phthisical patients admitted into the workhouse hospital were labourers and mill operatives. Dr. A. Gardner Robb, physician to Purdysburn Fever Hospital, said that the present accommodation for infectious diseases was not sufficient. They had sufficient ground at Purdysburn Hospital to enable them so to extend it as to double the accommodation if necessary. Mr. C. J. Milligan, Dr. James Martin, and Dr. R. J. Munn, dispensary medical officers, were then examined as to the condition of their districts. Mr. James M'Kee gave evidence as to the cost of analysing food. He wanted recently to get three samples of milk analysed and was charged 5*s.* for each—that is, 15*s.* in all. He suggested that a nominal fee of 1*s.* should be the amount.

Cerebro-spinal Fever.

After an interval of two months since the last case of this disease was reported a young man, 16 years of age, resident at a place in the country midway between the towns of Lurgan and Portadown, was taken ill with this disease and on July 16th was removed to Lurgan Workhouse Infirmary, where he died on July 18th, the attack having been very severe. This is the fourth case in Lurgan Union which has proved fatal. During the week ended July 13th eight cases of cerebro-spinal meningitis were reported in Belfast, as compared with six in the previous week, and since the last meeting of the public health committee on July 11th up to July 18th only four cases had been notified. Although the large number of ten deaths occurred from the disease in the week ended July 13th it did not indicate any fresh increase in the epidemic. A most interesting point has been worked out at the pathological laboratory of Queen's College, Belfast, by Dr. Thomas Houston and Dr. J. C. Rankin. They have found that the cocci in the Glasgow, Edinburgh, New York, Philadelphia, and Hamburg epidemics are identical in their reactions, while, on the other hand, the cocci from the London cases do not react like those present in these epidemics. This raises the very important question as to the exact entity of the so-called posterior basic meningitis. Is it a sporadic form of the epidemic cerebro-spinal fever or is it a variety and not the same species of disease? Clinical experience in Belfast would support the view that posterior basic meningitis is not identical at all with the epidemic form and the work done in Queen's College laboratory is in the same direction. At a special meeting of the city corporation of Belfast, held on July 22nd, it was resolved that for a further period of six months, to date from July 1st, 1907, cerebro-spinal fever shall be a notifiable disease under the Infectious Diseases (Notification) Act of 1889.

(FROM OUR OWN CORRESPONDENT.)

Large Doses of Cryogenine in Tuberculous Fever.

M. Crespin, assistant professor at the School of Medicine at Algiers, read a paper before the Therapeutical Society on June 25th upon the results which he had obtained by the use of cryogenine in over 200 cases of tuberculosis. The fever of pulmonary tuberculosis is easily affected by cryogenine, whether given at the commencement of the disease or at its end. The dose to be given varies according to the case; being sometimes more than 2·50 grammes in the 24 hours. Patients suffering from pulmonary tuberculosis seem to have a singular tolerance for the drug and the best time to give it is just before the temperature may be expected to rise.

The Paris Faculty of Medicine.

The council of professors of the Faculty of Medicine of Paris has recommended to the Government for the chair of anatomy in the first place M. Nicolas, professor of descriptive anatomy at the faculty of Nancy, and in the second place M. Rieffel. For the chair of the history of medicine and surgery it has recommended in the first place M. Gilbert Ballet and in the second place M. Dupré.

Military Legislation for those Wounded on Active Service.

At the Society of French Military Medicine M. Demmler on July 4th gave examples of affections contracted on active service, the sufferers from which were unable to obtain sufficient relief owing to the state of the law bearing on the subject. At the same meeting M. Billet and M. Schuttelaer brought forward various modifications for an alteration in the law. M. Piot and M. Salle recommended an improved organisation of the military thermal hospital stations and the methodical employment of all their therapeutic resources for the treatment of the consequences of wounds. This proceeding, they argued, would largely diminish the incapacity for work from which patients of this class suffer.

Accumulators on Tramcars.

M. Gautier has brought before the council of public oxygen. The reaction, he remarks, by which the oxygen is evolved is no ordinary one, for the evolution is not constant or continuous. It is greatest in the sunlight and ceases often on a dark day, to commence again on a bright one, and the reaction goes on slowly in this way for months when it apparently ceases. If the water is renewed, however, the reaction starts again; in other words, a small amount of the scale would seem to be capable of oxygenating a large amount of water. When the receptacle contains a large amount of mineral water in contact with a layer of pan scale oxygen gas appears to be given off indefinitely. On examining the water and the scale under the microscope the presence of infusoria was revealed. Scale that had been ignited no longer gave oxygen in contact with water. The conclusion seems to be that the evolution of oxygen is due to the presence of infusoria in the scale, but it is difficult to understand how living infusoria can survive the evaporating process in the pan. The infusoria, if present, must have attached themselves to the scale after it had been removed from the evaporating pans. The evolution of oxygen in this way is, at all events, a very interesting phenomenon, whatever the correct explanation of its formation may be.

CHLORIDE OF SODIUM AND HEART DISEASE.

ACCORDING to an editorial article in the *Indian Medical Record* for May 28th the conclusions of R. Massalonga and G. Zambeli are that the chloride of sodium is a regulator of the humours, of osmotic pressure, of arterial pressure, and of the dehydration of the tissues, but is at the same time a factor in asystolic phenomena and the dropsy of cardiac disease; they have therefore practised the limitation of chlorides in the dietary of all cardiac cases for several years, and they find that this limitation of chlorides soon restores the equilibrium and arrests all unfavourable symptoms. They, however, insist upon the supplemental use of diuretics or heart tonics which accelerate the cure of such cases. The chloride-free diet itself acts as a diuretic as it helps the removal of the œdema which remains as an obstacle to the heart's action, which once thus freed increases its own energy and tends to re-regulate its own function. Widal is another fervent supporter of this chloride-free dietary. It has been noted with reference to the elimination of the chlorides, continues the writer, that it varies in direct proportion to the amount of physical signs and symptoms present, for when the cardiac lesion is not productive of distress its elimination is normal, whereas when dyspnœa or evening œdema supervenes the elimination of chlorides is found to be deficient. The good results obtained in cardiac cases with an exclusively milk diet will now find an explanation in the comparative poorness of milk in salt (1·50 to 1·80 grains (*sic*) per litre). According to the writer in the *Record* the average individual consumes by far too much salt but as long as his kidneys do not refuse to carry off the excess all goes well. As soon, however, as inadequacy in these organs takes place from any cause and the chloride of sodium is retained an excess of water is absorbed to hold it in solution. Then the trouble begins, for the salt does not remain in the blood; it must pass into the tissues and in its passage it carries the water into them and in this way a condition of œdema has to be dealt with. A dechloridated diet means that a food is supplied devoid of one of the necessary elements required in tissue metabolism, and as this demand must be supplied the surplus in the tissues is called upon to do the needful, and so in its repassage back into the blood for its redistribution it carries with it the water which it had attracted, and so comes the reduction or disappearance of the œdema. We have thought it worth while to produce the foregoing abstract from the columns of our contemporary, merely making a few verbal alterations for the sake of clearness as the English of the article savours of the East. The subject is certainly one that calls for attention. Many people imagine that salt is a prophylactic against ill-health and that they cannot well consume too much of it. No doubt the value of common or table salt as an aliment is considerable, and the robust who make blood easily and rapidly can afford to take it in large quantities without injury. With delicate people, however, especially those whose thoracic organs are easily deranged, the habitual ingestion of more salt than is required by the system is sure to produce an ill-effect. The amount of salt that can be consumed daily with safety depends upon the constitution of the individual; it cannot be set down in precise terms like the dose of a quack nostrum.

EPIDEMIC CEREBRO-SPINAL FEVER.

WE have already referred to the continued presence of the meningococcus in persons who had recovered from the clinical symptoms as observed by Dr. R. M. Buchanan of Glasgow and the same peculiarity has been noticed by others. At a recent meeting of a medical society in Heidelberg Dr. Krayer said that he had been able to cultivate the meningococcus from cerebro-spinal fluid in which it was not discoverable with the microscope; in one case the organism continued visible for 170 days. In Scotland during the week ended July 20th there were 7 deaths from this cause registered in Glasgow, 3 in Edinburgh, and 1 in Leith. In Glasgow the weekly report issued on July 19th showed that there were at that time 56 cases under treatment.

RATS AND PLAGUE IN INDIA.

THE Trustees of the Indian Museum in Calcutta have published in pamphlet form at the price of 8 annas (about 7*d.*) a number of interesting particulars bearing on the identification of rats connected with plague in India. The pamphlet has been written by Dr. W. C. Hossack of the Plague Department, Calcutta, and in an introductory note Mr. N. Annandale, superintendent of the museum, states that a more detailed account by the same writer of the species occurring in Calcutta will be issued shortly by the Trustees in the first volume of the "Memoirs of the Indian Museum." Dr. Hossack says that the external differences between the various kinds of rats are so slight that, to one who is not an expert, specimens belonging to entirely different genera may present an apparently identical appearance. The most important body measurements are the lengths of the head and body, the tail, the hind feet, and the ears. These lengths are most accurately taken by sliding callipers, but a pair of compasses and a measuring rule or tape may also be used. The length of the head and body is taken from the tip of the nose, excluding hairs, to the centre of the vent. The length of the tail is taken from the centre of the vent to the tip of the tail, excluding hair. Minute directions are given for the preparation of skins and skulls, for the labelling of specimens, and for describing the colour of the animals according to Ridgway's scale of colours for the use of naturalists. Spirit is recommended as the most trustworthy medium in which to preserve specimens if skins cannot for any reason be prepared, but no time must be lost after the animal has been killed, or putrefaction may proceed even in the spirit. Carbolic acid may be added to the spirit in the strength of one ounce to the pint. Formalin may be used, but in India weak solutions are useless; the solution should never be under 15 per cent. strength of formalin—i.e., 6 per cent. strength of formic aldehyde, as formalin is a 40 per cent. solution of the latter. Dr. Hossack describes seven kinds of rat which are of importance in connexion with plague, two of them being mus rattus (the

99 had paid the debt (which in their case averaged less than £600) at the age of 41 years, and 69 (with a debt of £800) hope to be clear of it at the age of 51 years. Against this dark background the conspectus of the income of the Stockholm practitioners stands in a more pleasing light, for 50 per cent. of them have declared an income of more than £500, 12 per cent. an income between £400 and £500, and 28 per cent. an income below £400. It must be remembered that the cost of living is considerably less in Scandinavia and Denmark than in England.

(FROM OUR OWN CORRESPONDENT.)

Medical Changes at the Vatican.

IN Dr. Lapponi died the last of the "archiatri Pontifici." The economies effected by the reigning Pontiff in the administration of the Vatican have put an end to the office as well as to the name. There is now only a "medico privato di Sua Santità" (Dr. Petacci) with a "medico consulente" (Professor Marchiafava), neither holding a special position at the Pontifical Court, not even having the special uniform, so elegant and distinctive, which the "archiatri Pontifici" wore on state occasions. Other changes are not less notable. Dr. Lapponi, whom the present Pope's predecessor, Leo XIII., so highly esteemed, was nominated by that able and enlightened Pontiff director of the "servizi sanitari" of the apostolic palaces—an office of peculiar importance at the Vatican, as under Leo's reign there were frequently lodged within its area crowds of pilgrims of every nationality and clime, necessitating the most vigilant sanitary, hygienic, and medical supervision. In this capacity Dr. Lapponi displayed equal intelligence and skill, nowhere more than in the heating apparatus which was admirably effective. Leo XIII., indeed, took a personal interest in this as in all the duties of his "archiatro," down to examining the splendid microscope and the various cultures of micro-organisms which Dr. Lapponi used to submit to him from time to time. Pius X., however, has no such curiosity—caring only less for the wonders of bacteriology than for the novelties of practical hygiene, while contenting himself in the matter of heating with a simple brazier (*caldano*) placed in the anterooms leading to his private apartment. So long as Dr. Lapponi lived Pius made no further change to speak of, except indeed to suppress the lectureship on medical jurisprudence held by his "archiatro" with such acceptance. But now, as I have said, the old directorate of the "servizi sanitari" has been abolished with the title of "archiatro" itself—offices which entitled Dr. Lapponi to be present on state occasions and to be at hand, with control of the requisite *personnel*, should anything requiring medical aid occur at the audiences or receptions. An incident which saddened one of these functions not long ago was the sudden illness and death of a lady who was present—there being no one to give immediate aid except, by mere chance, a foreign physician who happened to be one of the audience. Such of the "servizi sanitari" as have been retained are under the care of two old medical attachés of the Vatican, Dr. Battistini and Dr. Masciarelli, who have no official connexion with the Court, who hardly ever know when or whom the Pope receives, and who have no such part in the disposal of the "servizi" as that formerly exercised by the "archiatro." Something like disorganisation of the "servizi" has been the consequence, the situation being practically this: Two medical men are available for the said "servizio" by day and two by night, either half of the 24 hours being thus provided for in case of medical assistance being required. A considerable number of supernumeraries, mostly medical aspirants, are, moreover, within call in case one or other of the two above-mentioned functionaries should have need of them. Every morning one of the two enters on his duties in the Vatican, visiting all the patients requiring attendance and remaining at his post for some time, in case of further eventualities. In the afternoon the visit is repeated but, as a rule, only *pro formâ*. The two relieve each other every 15 days and each receives 150 lire (£6) a month as a honorarium. Every evening one of the other two enters on his duties, in the winter months at 9 P.M., in the summer months at 10 P.M., and sleeps in the Vatican or in a dormitory close at hand, the said duties terminating at 7 A.M. The honorarium of each is 100 lire (£4) a month. The supernumeraries above referred to may be employed during the day or during the night and are paid at the rate of 60 lire (£2 8*s*. 4*d*.) a month. No medical post at the Vatican can be called lucrative—indeed, for some time past the subalterns have been taking steps to have an increase of pay or its equivalent; but their overtures have not as yet received much attention under the *régime* of economy that has set in. Still, the Cardinal Secretary of State has no difficulty in filling up vacancies—such is the ambition among many young physicians to serve the Holy See. At present the medical staff (leaving out the private physician of the Pope and his consultant) is composed of Dr. Battistini and Dr. Masciarelli for the daily "servizi," Dr. Amici and Dr. Cagiati for the night, and Dr. Gennari, Dr. Probi, Dr. Salvatori, Dr. Angeli, and others as supernumeraries. The corps of the "Guardie Nobili" has also its physician, Dr. Masciarelli; the Swiss Guard, Dr. Capparoni; and the "Guardia Palatina," Dr. Venturi and Dr. Calisti, all these being directly paid on a small scale by the corps to which they are attached, not by the Vatican itself.

The Climatic Stations of Italy, Thermal and Maritime.

May I draw your readers' attention to an official guide to the "Stazioni Climatiche Termali e Maritime d'Italia," issued by the Association for Promoting the Influx of Visitors? It is an excellent compendium of information likely to be useful to the British, Colonial, or American consultant, and is to be had gratuitously on application to the secretary of the association, Via delle Carrozze, Rome.

July 20th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Toxic Effects of Tobacco, Tea, and Coffee.

EXPERIMENTS conducted by Dr. Gross and Dr. Krämer in the Vienna physiological laboratory with a view of ascertaining the danger or otherwise connected with the use of some modern stimulants have brought out several interesting results. Both human beings and animals were examined and the number of the experiments was 250. It was found that the effects of tobacco are chiefly manifested in the circulatory and the alimentary systems. The action on the stomach is at first to stimulate secretion but this stage is of short duration, and a diminution of secretion then follows not only in the gastric mucosa, but also in the salivary glands. The muscular coats of the intestines are irritated so that spasmodic contractions are brought about. Colic, painful spasms of a characteristic type and lasting from five to 17 minutes, and thin motions are recognised effects of excessive smoking. Leucoplakia of the tongue is mostly associated with syphilis and occurs almost exclusively in smokers; its relation to cancer is generally admitted. As regards the action of tobacco on the circulatory system, it was found that the blood pressure rises soon after smoking, the apex beat becomes more distinct, and the pulse increases. Chronic tobacco poisoning has an injurious influence on the arterial walls in consequence of the increased blood pressure; it promotes arterio-sclerotic changes, and the changes in the blood-supply of the nerves of the heart and the eye produce those lesions which are known under the name of tobacco poisoning and which many observers regard as nervous, whereas they are in reality organic lesions. Cigarettes are especially injurious, because the smoke of the paper is added to the action of the tobacco. Tea and coffee are relatively much weaker poisons, at least in the form of beverages, as they are generally used. A cup of weak tea or coffee acts favourably on the secretion of the stomach, so that coffee taken in moderation may be regarded as a stomachic, but excessive coffee drinking continued for a long time produces spasms of the involuntary muscles, tremor of the hands, palpitations, and atony of the stomach. It is difficult to draw a distinction between the effects of the above-mentioned substances, because in general at least two of them, if not all three, are habitually used. When total abstinence from them is not possible a very good plan for combating the ill-effects is found to be the observance of "free days," that is, of days when tobacco, coffee, and tea are either abjured by the patient or else used in very small quantity only. By allowing the organism to rid itself of the accumulated poison and so restoring the

In the first four huts it was intended, and it happened, that wild rats should enter through, and build nests in, the roof, but they had no direct contact with the experimental animals, being separated from them by the wire ceiling built in under the roof of the hut. These differences had only one effect. The supply of fleas reaching the animals in the huts varied in accordance with the number of wild rats above them and the amount of light admitted to the huts, darkness being the more favourable condition for fleas. It was attempted to keep the two huts with impervious roofs absolutely free from fleas, but this was not found possible. The experiments were elaborate and ingeniously devised, and their course was constantly controlled by "flea-censuses" repeatedly held on animals taken from the various huts; these were accomplished by chloroforming the animals, and incidentally the fleas they harboured, combing out the latter and counting them. Unexceptionable bacteriological evidence was obtained of the cause of death of every animal that died. The animals employed in the observations were chiefly guinea-pigs and the experiments were divided into six series. The method adopted was to place together in the same hut healthy and inoculated guinea-pigs, the variable quantity in the experiments being the flea-supply from the roof, as we have already indicated. The experiments in some cases lasted nearly two months and the results of the various series are thus summarised in the report after a description of the experiments in detail.

Series A (six experiments) showed that epidemic plague did not occur when healthy guinea-pigs lived in close contact with plague-infected guinea-pigs under conditions where access of fleas was prevented, but that under otherwise similar conditions plague spread among the healthy animals in places where fleas were abundantly present. It is noteworthy that the huts were not cleaned out during the whole time (one or two months) occupied by these experiments and the animals took their food from the floor which was contaminated by the excreta of their sick companions. In these circumstances, although an occasional guinea-pig succumbed to plague, the disease did not spread epidemically in the absence of a flea-supply.

Series B consisted in one experiment in which the transference of fleas from guinea-pigs dying from plague started an epidemic in an uninfected hut which, by the introduction of fresh fleas, was maintained.

Series C (three experiments) showed that when an epidemic has occurred among a number of guinea-pigs the contagion still remains in the place and is effective in proportion as the animals are accessible to, and found to be infested with, fleas.

Series D was a single experiment and showed that fleas removed from infected guinea-pigs and isolated in test-tubes can convey plague to healthy animals on which they are allowed to feed.

Series E and F were also single experiments. *E* showed that plague is not conveyed from mother to offspring in the absence of fleas. In *F* two monkeys were used and one was exposed without harm in a plague-infected cage in which it was protected from fleas by a layer of "tangle-foot" (i.e., a sort of sticky fly-paper) which surrounded it. Another monkey, not protected from fleas, succumbed to plague.

Other general conclusions of these experiments are thus summarised: 1. If fleas are present then the epizootic once started spreads from animal to animal, the rate of progress being in proportion to the number of fleas present. 2. An epizootic of plague may start without direct contact of healthy animal and infected animal. 3. The conclusions of Part II. that the rat flea can convey plague from rat to rat are confirmed. 4. Infection can occur without any contact with contaminated soil, as in certain of the experiments the animals were raised in cages from the ground. 5. Aerial infection is excluded, as guinea-pigs suspended in a cage two feet above the floor did not contract the disease, whilst in the same hut the animals running about became infected.

In these experiments the buboes developed in the infected animals in the following situations.

Bubo in one situation, 162 (90·5 per cent.): neck, 144 (88·9 per cent.); groin, 15 (9·3 per cent.); and axilla, 3 (1·8 per cent.).

Buboes in two situations, 13 (7·2 per cent.): neck and groin, 10 (77 per cent.); and neck and axilla, 3 (23 per cent.).

Buboes in three situations, 2 (1·1 per cent.)—i.e., axilla, neck, and groin, 2 (100 per cent.).

No bubo, 2 (1·1 per cent.).

4. (iv.). *Experiments in Plague Houses in Bombay.*—The next series of experiments was carried out in houses infected with plague in Bombay. They were made in rooms in which two or more people were suffering from the disease or in which rats suffering from plague or dead had been discovered. The report points out that these conditions did not render it absolutely certain that the rooms were infected, as the patients might have contracted the infection elsewhere and some of the rats might have died from poison and not plague. The method adopted was the letting loose of guinea-pigs under varying conditions in the rooms, followed by an unexceptionably complete bacteriological investigation into the cause of death of all those that succumbed. The experiments are described in three groups of two series each.

In *Group 1* guinea-pigs were allowed to run free from about 18 to 40 hours in the selected houses, a technique that was devised by Captain Liston. Following the results obtained in the other series of experiments special attention was paid to the number of fleas found on the animals, which were, moreover, carefully differentiated as human, cat, or rat fleas. In this group Series 1 dealt with guinea-pigs running free in plague houses that had not been disinfected; these animals were found to act as good traps for fleas, on an average 20 per room being obtained, most of them rat fleas. 42 experiments were done and in 12—i.e., 29 per cent.—those left in from 18 to 40 hours contracted plague, the bubo being situated generally in the cervical region. Of the 18 experiments in which more than 20 fleas were obtained 50 per cent. gave similar positive results. In Series 2, 31 observations were made in a similar manner in houses that had been previously disinfected, chiefly by washing the floors and walls with an acid solution of perchloride of mercury of strength 1 in 750; in a few burning sulphur was employed. The points observed were again the number of fleas caught on the guinea-pigs and the number that contracted plague. The former numbers were very large, the average being 40 per house. In nine houses the animals died from plague—i.e., in 29 per cent. of the experiments, this being the same number as was obtained in the non-disinfected houses. Of 13 cases in which more than 20 fleas were caught 36 per cent. gave positive results. The buboes were chiefly cervical. It has been abundantly proved that the disinfection processes kill all plague bacilli on the floors and walls, but they do not affect the flea inhabitants of the house; these observations afford strong support to the contention that fleas are the agents in spreading the disease.

In *Group 2* fleas obtained in plague houses were fed upon rats or guinea-pigs in flea-proof cages in the laboratory. In Series 3 the fleas were caught on plague-infected rats caught in the houses; three experiments were done, and in each case plague was transmitted to the animals in the laboratory. In Series 4 the fleas were caught on guinea-pigs and other animals which had been left for some hours in the plague houses; in 8 out of 40 experiments the laboratory animals which were supplied with these fleas contracted the disease.

In *Group 3* the experiments were contrived so that whilst all the experimental animals were protected from both floor and wild-rat infection half were protected from fleas whilst the other half were not. For each experiment a pair of animals was thus used. In Series 5, 42 experiments were made in which pairs of caged guinea-pigs, one protected from fleas by means of a fine wire gauze curtain, and the other not so protected, were placed side by side in a plague house. Both were equally subject to aerial infection. No protected animal caught plague, whilst four of the unprotected animals died from it, developing cervical buboes; many fleas were caught on them and none on the protected animals. Series 6 was performed with pairs of animals in suitable cages, one of which was surrounded with "tangle-foot" in order to prevent fleas from gaining access to it, and the other with sand which gave no such protection. It was found that no animal protected by a sufficiently broad layer of "tangle-foot" contracted plague, but 24 *per cent.* of the control animals did so. Out of 247 fleas caught on the "tangle-foot" 60 per cent. were human, 34 per cent. were rat, and 6 per cent. were cat fleas. Bacilli resembling bacillus pestis were demonstrated in the stomach contents of one out of 85 human fleas dissected, and of 23 out of 77 rat fleas. Tables are given in the report with full details of all the experiments done in this part of the investigation.

II.—The second paper in the report is a Note on the Species of Fleas *found upon Rats, Mus rattus* and Mus decumanus, in different parts of the world, and upon some variations in the

Fuller, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Herbert Gall, St. Bartholomew's Hospital; Harry Leon Gauntlett, King's College; Thomas Sidney Gibson, St. Bartholomew's Hospital; Bernard Goldsmith, Middlesex Hospital; Bernard Grainger Goodwin, Birmingham University; Samuel Richard Harrison, London Hospital; John Eric Hepper, St. Bartholomew's Hospital; Harold Howard Hiley, University College, Bristol; Gordon Alexander Hodgson, Leeds University; John Bowling Holmes, Manchester University; Thomas Robert Lloyd Jones, London Hospital; Latafat Hosein Khan, St. Bartholomew's Hospital; Sohan Lall, Lahore Medical College and London Hospital; Christian Frederic Louis Leipoldt, Guy's Hospital; Mark Lindsey, St. Bartholomew's Hospital; Thomas Parry Lloyd, Walter Everard Lloyd, and Donald Macrae, London Hospital; Horace Lloyd Mann and Edward Hillis Marshall, St Thomas's Hospital; Godfrey Kindersley Maurice, St. Mary's Hospital; Malcolm Melton Melrose, Manchester University; James Knowles Milligan, St. Thomas's Hospital; Joseph Morrey, Manchester University; Malcolmson Knox Nelson, Guy's Hospital; Burford Noel Norman, University College Hospital; Max Nurick, Liverpool University; Wilfrid George Orchard, St. Bartholomew's Hospital; Henry Locke Paddon, B.A. Oxon., Oxford University and St. Thomas's Hospital; William Robert Parkinson and Adrian Charles Paterson, St. Thomas's Hospital; Percy Vivian Giles Pedrick, L.D.S. Eng., Guy's Hospital; Alfred Spearman Pern, St. Thomas's Hospital; Allan Pimm, University College Hospital; Vivian St. Leger Pinnock, University College, Bristol; D'Arcy Power, St. Bartholomew's Hospital; John Arnoux Prendergast, University of Leeds; Maurice Dyball Price, Guy's Hospital; James Stanley Robertson, London Hospital; Lawrence Lancaster Satow, St. Bartholomew's Hospital; Henry Lionel Hughes Steele, St. Thomas's Hospital; Alan Murray Stuart, St. Mary's Hospital; William Francis Sutcliffe and Wilfrid Percy Tindal-Atkinson, St. Thomas's Hospital; Harold John Austin Tootal, St. Mary's Hospital; Charles Grimshaw Waddington, Leeds University; George Fred Walker, Liverpool University; William Watts, Manchester University; Thomas Alexander Weston, B.A. Cantab., Cambridge University and St. Thomas's Hospital; and Arthur White and Herbert White, St. Thomas's Hospital.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—M. L. Ford (Section II.), London Hospital; R. J. W. McKane (Sections I. and II.), Leeds; G. B Messenger (Section II.), Westminster Hospital; C. C. H. L. Moll (Section II.), Guy's Hospital; and C. S. Ormsby, St. George's Hospital.

Medicine.—E. R. Bastard and F. H. W. Brewer (Section I.), St. Bartholomew's Hospital; J. Brierley (Section I.), St. Thomas's Hospital; M. L. Ford (Section II.), London Hospital; F. B. O'Dowd (Sections I. and II.), Birmingham; H. W. Phillips (Sections . and II.), Manchester; S. K. Poole (Section II.), Guy's Hospital; G. Rollason (Sections I. and II.), Birmingham; and J. S. Ward (Sections I. and II.), Sheffield.

Forensic Medicine.—E. R. Bastard and F. H. W. Brewer, St. Bartholomew's Hospital; J. Brierley, St. Thomas's Hospital; L. G. H. Furber, St. Bartholomew's Hospital; A. J. Hopper, Durham; F. B. O'Dowd, Birmingham; R. Rowlands, Glasgow; E. E. C. Vollet, Paris; and C. J. Wolfe, Edinburgh.

Midwifery.—A. R. Hardy, Manchester; M. Rathbone, Royal Free Hospital; G. H. Rodolf, London Hospital; and E. E. C. Vollet, Paris.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: E. R. Bastard, M. L. Ford, A. J. Hopper, R. J. W. McKane, G. B. Messenger, E. E. C. Vollet, and J. S. Ward.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates satisfied the examiners:—

M.D. EXAMINATION.

Medicine.—Harold Edward Dyson, B.S., University College; Harry Finzel, B.S., St. Bartholomew's Hospital; Montague Leonard Hine, B.S., Middlesex Hospital; Thomas Lewis, B.S., University College; Reginald Henry Miller, B.S., St. Mary's Hospital; Robert Milne, B.S., London Hospital; Leonard Gregory Parsons, B.S., University of Birmingham; John Robert Steinhaeuser,* B.S., Guy's Hospital; Frederick George Thomson (University medal), University of Cambridge and Middlesex Hospital; and Ralph Osmund Williams, B.S., Guy's Hospital.

Pathology.—Thomas Swale Vincent, University of Birmingham, University College, and University of Edinburgh.

Mental Diseases and Psychology.—Philip Anthony Mark Green, London Hospital.

Midwifery and Diseases of Women.—Vincent Z. Cope, B.A., B.S., St. Mary's Hospital; Charles Dyson Holdsworth, B.S., University College; Eardley L Holland, B.S. (University medal), King's College; Helen Nora Payne, B.S., London (Royal Free Hospital) School of Medicine for Women; and Frank Thomas H. Wood, B.S., B.Sc., Guy's Hospital.

State Medicine.—Alfred Henry Gerrard, M.D., University College.

Tropical Medicine.—Ernest Edgar Maples, B.S., St. Bartholomew's Hospital and London School of Tropical Medicine.

* Obtained the number of marks qualifying for the University medal.

M.S. EXAMINATION.

Sidney Arthur Boyd, Charing Cross Hospital; Harold Collinson University of Leeds; Philip Maynard Heath (University medal) and Harold Turley Mant, University College; and Thomas Perrin, M.D., London and St. Thomas's Hospitals.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Paul Lazarus, Dr. Max Mosse, Dr. Leonor Michaelis, Dr. Ludwig Blumreich, and Dr. Josef Heilbron have been granted the title of Professor. Dr. Anton Steyrer, Dr. Jürgans, and Dr. Leo Mohr have been recognise *privat-docenten* of Medicine.—*Bologna:* Dr. Gaetano F of Naples has been recognised as *privat-docent* of Child Diseases.—*Bonn:* Dr. A. Hübner and Dr. Gustav Em have been recognised as *privat-docenten* of Internal Med and Dr. E. Zurhelle as *privat-docent* of Midwifery Gynæcology.—*Breslau:* Dr. Hermann Küttner of Mar has been appointed to the Chair of Clinical Surger succession to Dr. Garrè. Dr. A. Neisser, Extraordi Professor of Dermatology and Syphilis, has been prom to an Ordinary Professorship. Dr. Hannes has recognised as *privat-docent* of Midwifery and Gynæcolog *Brussels:* Dr. Heger is resigning the Chair of Physiol but retains his position as Director of the Solvay Institute *Budapest:* Dr. Johann Bokay, Extraordinary Professor Children's Diseases, and Dr. Alexander Koranyi, Ext ordinary Professor of Medicine, have been promoted Ordinary Professorships.—*Copenhagen:* Dr. O. C. V. Petersen has been recognised as *privat-docent* of Anatomy. *Cracow:* Dr. Roman Nitsch has been recognised as *priv docent* of Hygiene.—*Innsbruck:* Dr. Alois Lode, Ext ordinary Professor of Hygiene, has been promoted to ordinary professorship.—*Kharkoff:* Dr. K. Elenevski h been recognised as *privat-docent* of Pathological Anato and Dr. Jakushevich as *privat-docent* of Medicine.—*Kie* Dr. Hermann Pfannenstiel of Giessen has been appointe Ordinary Professor of Midwifery and Gynæcology, in su cession to Dr. M. R. Werth who retires.—*Königsberg:* D Draudt has been recognised as *privat-docent* of Surgery an Dr. Hofbauer as *privat-docent* of Gynæcology.—*Lund:* Dr Overton, Assistant in the Physiological Institute, Wurzburg has been appointed Extraordinary Professor of Pharma cology.—*Marburg:* Dr. Paul Leopold Friedrich, Professor o Surgery in Greifswald, has been offered the chair of Sur gery in succession to Dr. Küttner who goes to Breslau.—*Munich:* Dr. Albert Döderlein of Tübingen has bee appointed Professor of Midwifery and Gynæcology i succession to Dr. Winckel, who retires. Dr. Wilhel Lohmann has been recognised as *privat-docent* of Ophthalmology.—*New York (College of Physicians and Surgeons):* Dr. P. F. Chambers has been appointed Professor of Gynæcology.—*Prague (Bohemian University):* Dr. Ollokar Kutoirt has been recognised as *privat-docent* of Laryngology and Otology, and Dr. Anton Ostrcil as *privat docent* of Midfery and Gynæcology.—*Odessa:* Dr. I. Kiyanitzyn of Kharkoff has been appointed to the chair of Hygiene.—*Prague (German University):* Dr. R. Kretz of Vienna has been appointed Professor of Pathological Anatomy in succession to Dr. Chiari. Dr. Adolf Schenkel, Extraordinary Professor of Ophthalmology, has been granted the title of Professor.—*Rostock:* Dr. Riemer has been recognised as *privat docent* of Hygiene, and Dr. Reinmöller as *privat-docent* of Dental and Oral Diseases.—*Tübingen:* Dr. Menge of Erlangen has been offered the chair of Midwifery and Gynæcology in succession to Dr. Döderlein. Dr. C. Schlayen has been recognised as *privat-docent* of Internal Medicine.—*Vienna:* Dr. Rosthorn of Heidelberg has been appointed to the chair of Midwifery and Gynæcology recently held by Professor Rudolf Chrobak. Dr. Wilhelm Falta has been recognised as *privat-docent* of Medicine; Dr. Heinrich Neumann as *privat-docent* of Otology; and Dr. Paul Clairmont and Dr. Paul Albrecht as *privat-docenten* of Surgery.

THE CHARGES OF THE PUBLIC VACCINATOR.—Public vaccinators' charges have always caused some grumbling on the part of the guardians of the Wandsworth Union. They were among the first to reduce the fee from 5*s.* to 2*s.* 6*d.* A deputation of practitioners attended the meeting of the board on July 18th and Mr. E. R. Badcock, the spokesman, pointed out that each vaccination entailed considerable expense to the medical man who had to make an average of four visits to secure one fee. They left it to the board to deal justly. Mr. Badcock mentioned that the minimum fee was certainly not lucrative. It was not the intention of the Local Government Board that fees should be reduced without regard to circumstances. A lady guardian asked whether the medical men did not receive a capitation fee of 1*s.* for each child on the vaccination officers' lists. Mr. Badcock replied that that was so but pointed out that in each case a communication had to be written and an appointment made to attend. Another member of the board asked whether a well-known local medical man had not stated that he considered 2*s.* 6*d.* a very good price, and whether many persons were not privately vaccinated for that charge. He was with the view of settling the questions: (1) as to whether it was possible to produce the disease in animals by feeding, and (2) as to whether this method of transmission played an important part in the epizootic or epidemic spread of the disease. The Indian Plague Commission (1901) pointed out that while three workers in India—namely, Gibson, Hankin, and Simond—had failed to infect rats by means of feeding, both the German and Austrian Plague Commissions had been able to give the disease to animals by this method. Kolle (1901), Kister and Schumacher (1905), Berestneff (1906), and Klein (1906) also successfully conveyed plague to rats by feeding them with infective material.

The experiments carried out by the present Commission may be briefly summarised as follows: 415 wild Bombay rats (Mus rattus and Mus decumanus) were given one meal consisting of about one-eighth of the viscera of a rat or guinea-pig dead from acute plague; 16 per cent. died within five days from acute plague, and in all 21 per cent. were infected. In comparison with these animals a series of rats (Mus rattus) caught on ships in Bombay, and which presumably had not experienced any epidemic of plague, were fed in the same way and 44 per cent. were infected. A further series of wild Bombay rats were fed on the whole carcasses of dead plague rats—i.e., including bone and other hard material—and 38 per cent. were infected. Similar experiments were also made in the Punjab with Mus rattus: of 28 animals which each received one half of the liver and spleen of a plague rat, 19 (68 per cent.) died all from acute plague in five days.

The writers direct especial attention to the post-mortem appearances of the rats thus infected by feeding. These differed markedly from those seen in naturally infected rats in that subcutaneous hæmorrhages were uncommon, the intestines were congested with hæmorrhages and ulceration of Peyer's patches, and three-quarters of the animals with buboes had mesenteric buboes which do not occur in naturally infected rats. These observations afford very strong evidence that rats in nature are not infected by feeding as has been often surmised. The paper concludes with a record of experiments, in which 194 rats were fed with urine from 35 cases of acute human plague; none of the animals became infected.

XIV. *On the significance of the localisation of the primary bubo in animals infected with plague in nature.*—Almost all observers are agreed in the opinion that the primary bubo develops in the glands in connexion with those lymphatics by way of which the plague bacillus has entered the body. Hunter (1904–06), on the other hand, holds that the primary bubo is merely an enlargement of a group of glands in the course of an acute septicæmic disease and is no indication of the path by which infection has taken place. In the present report experiments are detailed showing that the primary bubo develops in those groups of glands which are in direct lymphatic connexion with the skin area through which the plague bacillus gains an entrance into the body. Analysis of the records of a large number of animals infected naturally and in the laboratory gave the following results as to the localisation of buboes. Of rats found infected with plague in nature in the plague season in Bombay, in the off-plague season in Bombay, and in the Punjab villages, 72, 73, and 57 per cent. had cervical buboes and none had mesenteric buboes; three series of rats infected in the laboratory by the transmission of infected fleas showed cervical buboes in 67, 50, and 61 per cent. and no mesenteric buboes; while of rats infected by feeding only 36 per cent. showed cervical buboes and 72 per cent. had mesenteric buboes. The following table summarises these observations as shortly as possible:—

Table showing the Percentage Frequency of Buboes in Different Parts.

—	Naturally infected.	Infected by fleas.	Infected by feeding.
Rats examined ...	5183	117	119
Rats without buboes	16 per cent.	18 per cent.	8 per cent.
Cervical bubo	72 ,,	61 ,,	36 ,,
Axillary ,, ...	23 ,,	22 ,,	1 ,,
Inguinal ,, ...	18 ,,	35 ,,	1 ,,
Mesenteric ,, ...	0 ,,	0 ,,	72 5 ,,

The writers conclude, therefore, that *naturally infected* *by feeding* and that these results afford additional evidence that they are infected by the agency of fleas. A similar series of analyses shows that the distribution of buboes in guinea-pigs artificially infected by fleas is identical with the distribution in those animals which become infected in sequence to being placed for a few hours in plague-infected houses in Bombay.

XV. *Further observations on the transmission of plague by fleas, with especial reference to the fate of the plague bacillus in the body of the rat flea (Pulex cheopis).*—It was previously shown by the writers[4] that plague may be transferred from rat to rat by the transference of fleas from a septicæmic to a healthy animal. In the present communication the following questions are dealt with:—

1. The fate of the plague bacillus in the body of the rat flea.
2. Whether a single rat flea can transmit the infection.
3. Whether both male and female rat fleas can transmit the infection.
4. Whether other species of fleas can transmit the infection.
5. The mechanism by which the flea infects a healthy animal.

The results of the investigation of these points may be summarised thus:—

1. The average capacity of a rat flea's stomach is approximately 0·5 cubic millimetre. On this basis a flea imbibing the blood of a plague rat showing a good septicæmia might take as many as 5000 germs into its stomach.
2. Multiplication of the plague bacillus takes place in the stomach of the rat flea.
3. The approximate proportion of fleas in the stomach of which multiplication of plague bacilli takes place has been determined and it has been shown that this proportion varies with the season of the year, being six times greater in the epidemic season than in the non-epidemic season.
4. Plague bacilli are present in the rectum and fæces of fleas taken from plague rats and such fæces are infective to guinea-pigs both by cutaneous and by subcutaneous inoculation.
5. On rare occasions plague bacilli have been found in the œsophagus, but never in any other region of the body, such as the body cavity or salivary glands.
6. During the plague season fleas might remain infective for 15 days after imbibing infective blood, but during the non-epidemic season no animal was infective after the seventh day.
7. A single rat flea may transmit the disease.
8. Both male and female rat fleas can transmit the infection.
9. Experimenting with cat fleas (Pulex felis) and human fleas (Pulex irritans) 27 experiments with the former were unsuccessful, and out of 37 experiments with the latter three successes were obtained. Two experiments were made with Ceratophyllus fasciatus; both were successful. Multiplication of the plague bacillus takes place in the stomach of the human flea.
10. The plague bacillus has never been seen in the body cavity or in the salivary glands of infected fleas.

Evidence has been obtained to show that the bite of a healthy flea affords a sufficient avenue for infection by septicæmic blood if it is spread upon the bitten part. No evidence has been obtained in favour of infection by contaminated mouth parts or regurgitation from the stomach, but the possibility of infection by such means cannot be excluded.

XVI. *Experimental production of plague epidemics among animals.*—We have summarised above several series of experiments which had as their object the determination of the relative importance of the Indian rat flea, Pulex cheopis, and of actual close contact in the absence of fleas in the dissemination of plague from animal to animal. These observations were carried out in a series of small go-downs or cabins which were built especially for the purpose. The experiments recorded in the second report are a continuation of those already published. They were carried out during the off-plague season of 1906 and the plague season of 1907. In the first paper the structure of the go-downs was described in detail, but it may be repeated that the essential difference between them lies in the structure of the roofs. The roofs of four of the go-downs are tiled with material which offers protection and shelter to the wild rat of Bombay; the flea supply in the interior is therefore more or less abundant. The roofs of the two remaining go-downs are constructed of already obtained in the sanatorium. The Woolwich pality, he said, had sent patients since 1903 to Mait- Cottage, seven beds being now supported by Woolwich. cases had been sent on his selection, and on their arge he had observed them after their return to k. Out of 42 patients half, he said, were now at work. re had been ten deaths, and of the balance some had apsed, some had emigrated, and some had been lost sight . In his opinion the results of such sanatorium treatment ould be even more satisfactory could the patients be ardened by a graduated system of work in a labour colony. A sudden return to ordinary conditions of life and labour was often followed by a relapse, whereas he had noticed that those cases in which it had been possible to continue treatment for over six months had apparently been cured or were continuing to improve. The sum appealed for by Dr. Carling is £10,000, to be applied as follows: £4000 to be invested as an endowment fund; £2000 to acquire a farm adjoining Maitland Cottage for the purposes of the labour colony; and £4000 for necessary extension of buildings and equipment. So far a charge of 30*s*. per week per patient has just covered working expenses. It is estimated that a charge of 15*s*. per week will be sufficient to maintain without loss to the institution those kept on as workers, owing to their labour making them partially self-supporting. This is taking into consideration that the initial expenses are met by the public. The extension proposed will provide accommodation for 50 adult patients and 10 children, for whose benefit it is hoped that a sanatorium kindergarten may be started. It will be seen that an experiment of considerable social interest is here projected and one which it seems to us the public may well be invited to support. It should be added that the site, being on a spur of the Chilterns in beautiful common land, is an admirable one for the proposed extension.

THE SECOND INTERNATIONAL CONGRESS OF PHYSIO-THERAPY.—The English secretary, Mr. W. Deane Butcher, Holyrood, Ealing, London, W., asks us to remind our readers that this congress will be held at Rome from Oct. 13th to 16th and that the Italian Minister of Public Works has granted special travelling facilities on all lines both on the mainland and on the islands. Books of coupons will be issued to each member or associate of the congress by the organising committee. The coupons, which will be valid from Oct. 1st to Nov. 15th, will enable the holders to travel at a reduction of from 40 to 60 per cent. on ordinary fares.

A SHORT vacation course of 24 demonstrations and lectures will commence at the Post-Graduate College, West London Hospital, on Monday, August 12th next. Practitioners wishing to join this course or desiring further information about the Post-Graduate College should apply to Mr. L. A. Bidwell, the dean, at the hospital.

AN ASSOCIATION OF POOR-LAW INFIRMARY MATRONS.—A meeting was held at the Chelsea Infirmary on July 22nd to consider the advisability of forming an association of Poor-law infirmary matrons. It was agreed unanimously that such an association was urgently required. A constitution was drawn up and it was decided to hold quarterly meetings for the discussion of questions of interest.

ENNOBLEMENT OF A BAVARIAN PHYSICIAN.—Professor Friedrich Müller of Munich, who was invited to accept the vacant chair of medicine in Berlin, but preferred to remain where he was, has received the order of the Bavarian Crown, which implies a patent of nobility.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Glasgow Medical Men and the Notification of Births.

IN the Glasgow Corporation Bill, which came before the Police and Sanitary Committee of the House of Commons on July 17th, there was a clause making provision for the notification of births within 48 hours of their occurrence.—Dr. A. K. CHALMERS, the medical officer of health of Glasgow, Dr. MARY T. GALLAGHER, and other witnesses gave evidence to the committee in strong support of the clause.—Mr. HAROLD BEVERIDGE, one of the counsel for the Glasgow corporation, explained to the committee that the medical faculty had held a meeting in Glasgow and had intimated that they wished to be relieved of the duty of notification.—After some discussion the chairman of the committee, Mr. CORRIE GRANT, intimated that the clause must be put in agreement with the Huddersfield clause which imposed the duty of notification upon the medical man in attendance at the time of the birth and also provided for the payment of 1*s*. for each notification.—Mr. BEVERIDGE, after consultation with the members of the corporation of Glasgow, intimated that if the committee insisted on the inclusion of the provision regarding the payment of 1*s*. the promoters would prefer to drop the clause and to wait for the passing of the public Bill which was now before Parliament.—The clause relating to the notification of births was then deleted from the Bill.

A Scottish Vaccination Bill.

Lord HAMILTON of DALZELL has introduced a Scottish Vaccination Bill into the House of Lords. It has been read a first time. Its object is "to amend the law with respect to vaccination in Scotland by authorising a statutory declaration of conscientious objection."—Lord BALFOUR of BURLEIGH has given notice that he intends to move the rejection of the Vaccination (Scotland) Bill when it comes up for second reading.

Public Health Acts (Scotland) Amendment Bill.

The Public Health Acts (Scotland) Amendment Bill, which Lord HAMILTON of DALZELL introduced in the House of Lords on Monday, it is understood, relates to the notification of tuberculosis. Local authorities have felt themselves hampered by the existing law and the Bill, it is believed, proposes certain relaxations in reference to such matters as certificates for children attending school and the carriage of infected persons in public conveyances.

The Dairies, Cowsheds, and Milkshops Order.

The return which was ordered on the motion of Dr. RUTHERFORD showing the names of the councils of boroughs and urban and rural districts which made regulations under the Dairies, Cowsheds, and Milkshops Order of 1885, and also the number of councils of each class which have not any such regulations, has now been published as a Parliamentary paper.

The Notification of Births Bill.

The course of the Notification of Births Bill, which was introduced into the House of Commons by Lord ROBERT CECIL, is not likely to be so smooth as was hoped by its promoters. It has passed through a Standing Committee of the House, but two pages of amendments have been put down by various members for consideration when the report stage is taken.—Sir HENRY KIMBER has given notice that he will move the re-committal of the measure "for the purpose of amending it in several respects, particularly by striking out the provision that medical practitioners and midwives should be compelled to furnish the notification in question."

HOUSE OF COMMONS.

WEDNESDAY, JULY 17TH.

Fees under the Vaccination Bill.

Mr. DUNDAS WHITE asked the President of the Local Government Board whether, in view of the fact that under the present law the fees which conscientious objectors to vaccination had to pay for exemption certificates were public moneys, he would say why it was proposed that part of the fees for making the statutory declaration which it was proposed to substitute for these certificates should go to commissioners for oaths and other private persons.—Mr. JOHN BURNS replied: Justices' clerks are remunerated by salary and any fees received by them have to be paid over to the fund from which the salary is defrayed. Commissioners for oaths do not receive any salary and consequently they retain the fees paid to them.

A Chester Vaccination Order.

Mr. MOND asked the Secretary of State for the Home Department whether his attention had been called to the fact that in the Chester city police court on Wednesday, July 3rd, 1907, upon the hearing of an information under the Vaccination Acts against Thomas Boden, a threat was made both by the magistrate's chief clerk and the chief constable, that in consequence thereof his licence as a lodging-house keeper might be taken from him; and whether he would take the necessary steps to prevent any such course, seeing that no provision for it was authorised by any Act of Parliament, and the prescribed penalties under the Vaccination Acts were imposed upon the defaulter.—Mr. GLADSTONE answered: It appears that on the 3rd inst. an order was made for a child of Thomas Boden to be vaccinated within 28 days and no further proceedings had been taken. The clerk to the justices remarked that as Boden kept a common lodging-house possibly the corporation committee might consider the question of refusing the licence if a child was not vaccinated, and the chief constable acquiesced in this remark. No threat was made and the clerk has no control over the committee who deals with the licensing of lodging-houses. I cannot take any action in this matter.

THURSDAY, JULY 18TH.

Fatal Accidents in the United Kingdom.

Mr. LAIDLAW asked the Secretary of State for the Home Department how many fatal accidents were reported as having occurred in the United Kingdom in the years 1904, 1905, and 1906 respectively.—Mr. GLADSTONE (by printed answer) replied: The number of deaths in England and Wales due to accident or negligence was 10,902 in 1904 and 10,829 in 1905. The figures for 1906 are not yet available. The number in Ireland was 1675 in 1904 and 1568 in 1905; the number in Scotland in 1904 (the last year for which figures can be given) was 2594.

A Vaccination Case at Croydon.

Mr. LUPTON asked the President of the Local Government Board

DECENNIAL SUPPLEMENT FOR 1891-1900 TO THE SIXTY-FIFTH ANNUAL REPORT OF THE REGISTRAR-GENERAL.

PART III.[1]

IN dealing with that portion of his report which treats of the causes chiefly responsible for English mortality in the decennium last ended Dr. Tatham has prepared an interesting table showing the balance of loss and gain in the fatality of certain diseases. From this we learn that, as compared with the preceding decennium, an average annual life saving of 540 persons has been achieved in each million of the population during the period referred to.

Among the causes of death specified in the table an increased mortality was shown in nine—viz., measles, influenza, diphtheria, diarrhœa, pneumonia, tuberculosis (other than tuberculous phthisis, peritonitis, and meningitis), cancer, diabetes mellitus, and Bright's disease. The remaining diseases, 15 in number, showed in each case a reduced mortality. The mortality from small-pox in 1891-1900 was lower than that of the 10 years immediately preceding by 80 per cent. But a mere statement of the recorded death-rate gives an imperfect idea of the extent to which a community has suffered from small-pox. Unfortunately, the returns under the Infectious Diseases Notification Acts of 1889 and 1899 are not yet sufficiently complete to measure the incidence of sickness from this disease throughout the country generally. They are, however, complete for the administrative county of London, where the Act for the compulsory notification of infectious diseases has been strictly enforced since 1890. The actual number of cases notified from time to time appears in Sir Shirley F. Murphy's returns which are published weekly by the Registrar-General. Our readers will remember that in the years 1893-95 London experienced a serious outburst of small-pox. In the then existing vaccinal condition of the community terrible suffering and loss of life would have followed had it not been for the prompt removal of first cases; but this removal, thanks to the coöperation of the Metropolitan Asylums Board, was secured in practically every case. Nevertheless, the recorded mortality, which in no single year exceeded 5 in 100,000, conveyed no adequate warning of the danger. In the metropolis the information concerning the vaccinal condition of the small-pox cases contrasts favourably with that in other parts of England; for whilst in London the proportion of cases reported without statement as to vaccinal protection amounted to not more than 30 per cent., it exceeded 70 per cent. in the provinces. In the ten years ended 1900 there were registered in London 432 deaths, against 3626, or about eight times that number, in extra-metropolitan England. In London the proportion of cases stated to have been vaccinated was 30 per cent.; in the provinces it was only 12 per cent. In the former area the unvaccinated cases are stated to have constituted 40 per cent. of the whole; in the latter area, 18 per cent. only.

In the present report an interesting account is given of the behaviour of fatal influenza in this country from the time of its first appearance in epidemic form some 18 years ago down to the present time. Until the year 1890 England had been practically free from influenza mortality for more than 30 years. The mortality directly attributed to this cause in the quinquennium ended 1889 averaged no more than 3 per 1,000,000 of the population. Towards the close of 1889, however, influenza invaded our ports from the continent and thenceforward it appears to have established a foothold in this country. In 1890, the first complete year of the epidemic, influenza was returned as the cause of death in 4523 instances; in the following year the deaths rose to 16,686, and in the next the number was 15,737. The mortality due to this cause averaged 361 per 1,000,000 in the ten-year period ended 1900. In no single year of the ten did the rate fall below 122 per 1,000,000, which was the proportion recorded in 1896. At all ages of both sexes the mortality from influenza in the recently ended decennium does not greatly differ from that of the epidemic years 1847 and 1848, but at ages from 15 to 65 years the disease seems to have been more fatal in the later than in the earlier period, whilst at ages below 15 and above 65 years the reverse appears to have been the case.

Among the diseases that showed increased prevalence in the decennial period under notice the most important from a public health point of view is diphtheria, the mortality from which affection showed an increase on the rate of the preceding decennium of not less than 72 cent. The actual incidence of this disease is now more accurately expressed by the mortality returned under the head of diphtheria than was formerly the case. Nevertheless, the mortality is still probably understated in the tables, for it is known that a considerable portion of the deaths ascribed to such conditions as "tonsillitis," "quinsy," "ulcerated throat," "catarrhal laryngitis," &c., are really diphtheritic in character. With the more general adoption of bacteriological methods of diagnosis it is probable that a still larger proportion of these deaths will be returned as diphtheritic. At any rate, it is satisfactory to learn that the mortality under every one of the indefinite headings just mentioned has steadily fallen in recent years. It is important to remember that the Royal College of Physicians of London has recently decided that the terms "membranous laryngitis" and "membranous croup" are not henceforth to be used as synonyms for diphtheria. Until the year 1855 diphtheria was not distinguished from scarlet fever in the returns of the Registrar-General. In 1861-70 there were registered in this country no fewer than 52,545 fatal cases of "croup," but only 39,454 of "diphtheria." If it be assumed that what is commonly called "croup" is a definite disease distinct alike from diphtheria and from spasm of the glottis, it is remarkable that, in spite of the enormous increase of the population, the deaths from "croup" should have fallen from an average of more than 5000 annually in 1851-60 to an annual average of fewer than 600 in the five-year period last ended. When the recorded mortality from diphtheria is combined with that from croup the age-incidence of that mortality in the earlier decennia tallies more nearly with the known incidence of diphtheria at the present day than would have been the case had the formerly predominant factor of croup been left out of account. At the present time the combined mortality from diphtheria and croup is lower than it was 40 years ago.

Enteric fever is one of the diseases the fatality of which has decreased in this country almost *pari passu* with the improvement of local sanitary conditions. Until the year 1868 this disease was grouped with typhus fever and with so-called simple continued fever under the heading "Fever." But in the latest edition of its nomenclature the Royal College of Physicians directs that the names "simple continued fever" and "febricula" should no longer be used. In order to afford graphic illustration of the incidence of enteric fever mortality since 1868 a chart has been prepared for this report showing the corrected death-rates in each of the 37 years elapsed since this disease was first differentiated from other continued fevers. From this chart we learn that the rate of mortality has fallen from 384 per 1,000,000 in the year 1869 to 89 per 1,000,000 in 1905. But although the chart shows a great reduction in the loss of life from this disease it is doubtful whether it fully expresses the amount of that reduction. For whereas in the first quinquennium after 1868 an annual average of 4250 deaths were attributed to simple continued fever, the deaths thus returned in the quinquennium ended 1900 were fewer than 130 annually. There is little doubt, says Dr. Tatham, that many of the deaths referred in 1869-73 to continued fever were really due to enteric fever and the age distribution of these cases tends to support this contention. If this be correct, it follows that in recent years the reduction in enteric fever mortality has been greater than that indicated by the chart.

Pneumonia is one of the important diseases the fatality of which has recently increased considerably. Far greater importance now attaches to the incidence of this disease from the circumstance of its known relation to insanitary surroundings. In the latest edition of its nomenclature the Royal College of Physicians classes lobar pneumonia as a definitely infectious disease and pathologists now generally regard all forms of pneumonia as infective, although the infecting organism is not always the same. In the course of the first three decennia of the past 40 years there appears to have been little change in the mortality ascribed to pneumonia, but in the decennium last ended the rates show a decided increase. Locality appears to influence very seriously the prevalence of fatal pneumonia, to say that compensation would be paid. The number of cases last year was 632, against 519 for the previous year—a considerable increase; but it should be noted that in 1899 the number was 1268 and in the year 1900 it was 1058. Therefore they had the consolation of knowing that the average number had been reduced by something like 50 per cent. since that time. Although the reduced figures might give some satisfaction they in no sense afforded any reason for the relaxation of efforts to stamp out industrial diseases. The condition of things could not be described as satisfactory until they had been reduced to an absolute minimum. During the past year the Home Office had endeavoured to cope with this question. They had made regulations for the safety of workers in the trade of grinding paints and colours. The earthenware trade regulations were about to be overhauled, and it was hoped that this would effect a large reduction in the cases of lead poisoning. He went on to say that the fish-curing industry was being made the subject of a special inquiry with a view to decide what would be the best mode of revising the regulations with regard to . The inquiry would specially include the question of sanitation which was one of great gravity. The medical inspector's reports on this industry were voluminous but such portions of them as could properly be published would be issued with the report of the inquiry. The Departmental Committee on Industrial Diseases regretted that it could not recommend the scheduling of fibrosis of the lungs, although it was a disease which could be definitely traced to certain industries. In its early stages it was indistinguishable from ordinary cough or bronchitis, and the result of scheduling it would be prejudicial to workmen who might lose their employment on mere suspicion that they were developing the disease. The view of the Committee was supported by the Grinders' Trade Union which urged the Committee not to schedule the disease. Dr. J. S. Haldane took the same view and said that to schedule the disease would be disastrous to the tin mines of Cornwall. Dr. Oliver, one of the greatest authorities on dangerous trades, took the same line and said that on the whole it was not to the advantage of the workmen that this disease should be scheduled. With regard to the suggestion that naphtha poisoning should be scheduled, the Departmental Committee had come to the conclusion after visiting a number of indiarubber factories where the naphtha poisoning was alleged to have taken place that there was no industrial disease due to naphtha. The suggestion of the medical evidence was that the poisoning attributed to the naphtha was due to carbon bisulphide.

Vivisection.

Mr. SMEATON (who at a later stage of the proceedings moved the reduction of the vote by £100) complained that the vivisection law of 1876 was habitually disregarded and in some cases flagrantly violated. There was need for greater vigilance in this matter. For the past three years out of 89 581 operations on animals only 93 were made the subject of inspection at a cost of 2550 guineas. That was simply ridiculous—a flagrant waste of public money. There were two inspectors, one getting 600 guineas and the other 330 guineas. These gentlemen, although not at all times officers, received whole-time fees. The inspections were inefficient and far too rare. He considered that the Home Office took no steps to detect or investigate cases of unlicensed vivisection, consequently unlicensed operations would go on. Whereas great jealousy had been shown during the debate in regard to the inspection of workmen, dumb creatures were, in melancholy contrast to this, made the victims of men, who, although they ought to be restrained by the law, were convicted by the Blue-book of gross illegality and positive inhumanity and cruelty. He suggested that the inspectors should be increased in number and the Home Office should be put in a position to judge whether they had conducted their inspections efficiently

Mr. AKERS-DOUGLAS, as one who had held the office of Home Secretary, said that his experience of the Vivisection Act was that its administration as well as the conduct of the inspectors was most humane. He was certain that there was nothing like undue cruelty.

Mr. SMEATON (intervening) said that he never imputed it to the inspectors that they condoned cruelty but that they did not take the opportunity of examining the cases.

Mr. AKERS-DOUGLAS replied that the honourable Member had urged that sufficient care was not taken in granting licences. His experience went to show that every care was taken to see that licences were not scattered broadcast but were granted only to those who were authoritatively recommended.

Mr. GLADSTONE, in reply, said that the question of vivisection raised matters of extreme importance and complication. He could only, like his predecessors, exercise such common-sense as he possessed in the endeavour to secure the observance of the law with no want of humanity, but keeping sentiment with considerable strictness within the bounds of reason. It was impossible, he suggested, to carry matters in relation to this subject further pending the report of the Royal Commission. He assured Sir Charles Dilke that there was, and would be, no retrogression in the policy of the Home Office in regard to lead poisoning. They would do all in their power to stem the increase in the number of cases. With regard to life-saving apparatus in mines it was necessary at present to proceed with caution.

The debate on the Home Office Vote had not been concluded at 11 o'clock when it was automatically adjourned.

FRIDAY, JULY 19TH.

Infantile Mortality in Summer.

Mr. SUMMERBELL asked the President of the Local Government Board whether infantile mortality among the poorer classes usually rose greatly in the latter part of the summer and early autumn; whether the mortality would be reduced if parents who were unable to pay for a medical man for their children would apply for medical relief at an early stage of the children's illness; and whether he would advise the guardians to give all facilities to such parents to obtain medical relief for the children, and not to make it a debt or to offer it on condition that the parent went into the workhouse.—Mr. JOHN BURNS furnished the following written reply: I am aware that there is usually an increase in infantile mortality in the latter part of the summer and early autumn, especially in hot seasons, and it may be accepted, I think, that competent medical advice and treatment at an early stage of the illness would tend to reduce the mortality. I have, however, no reason to suppose that guardians are unwilling to afford medical relief for children whose parents are unable to provide it, or that persons properly entitled to receive medical relief are deterred from applying for it by the considerations referred to in the last part of the question If my honourable friend is aware of any cases of failure to give relief to the infants of parents unable to provide it, and will inform me of the particulars of such cases, I will consider them.

MONDAY, JULY 22ND.

Soldiers Succumb to Heat.

Mr. FELL asked the Secretary of State for War whether he could give the age of the two privates, Doyle and Sproute, of the 4th Argyll and Sutherland Highlanders, who were stated to have died from the heat on July 16th after the sham fight at Irvine Moor and the average age of the other 35 men who had to go to the hospital on the same occasion.—Mr. HALDANE answered: Private Doyle was 47 years of age and Private Sproute 44 years. Only 11 other cases due to heat were treated and all had returned to duty by the 18th. The average age of these men was 23 years.

Rabies in Rhodesia.

Mr. RIDSDALE asked the Under Secretary of State for the Colonies whether a consignment of dog muzzles had been recently ordered by the Rhodesian Administration for the purpose of stamping out rabies among native dogs.—Mr. CHURCHILL replied: It appears from the report of the Medical Director for 1906 that rabies, which first appeared in Southern Rhodesia in 1902, became more prevalent and more generally distributed in 1906 than in any previous year. Regulations were accordingly enacted with regard to the muzzling of dogs and other measures calculated to check the disease, and 20,000 muzzles have been ordered for distribution to natives. The chief native Commissioner of Matabeleland reports that the Matabele are much alarmed at the spread of the disease and are killing their own dogs in large numbers.

Inoculation for Plague.

Mr. JOHN ROBERTSON asked the Secretary of State for India whether inoculation for the plague continued to be practised in India in general and the Punjab in particular.—Mr. MORLEY gave the following reply: In all provinces inoculation is offered to the people and is performed free of charge by the district medical staff. In the Punjab of late it has been accepted by increasing numbers. In April last over 21,000 persons were inoculated in that province. The extent to which the remedy is used must necessarily rest with the people themselves, as no one is inoculated against his will.

The Southern Hospital, Carshalton.

Mr. CLELAND asked the President of the Local Government Board whether he was aware that a hospital called the Southern Hospital had been erected near Carshalton in Surrey by the Metropolitan Asylums Board; that the hospital was finished at the end of 1906 at a cost of more than £180,000 for expenses of erection, and that it was standing entirely unused at considerable expense of maintenance and danger of deterioration; whether there were any medical purposes to which it could be applied for the alleviation of infectious diseases; and, if so, whether he would direct the Metropolitan Asylums Board to find some use for this institution.—Mr. JOHN BURNS answered: I am aware that the managers have erected this hospital for fever cases and that it is not at present used for that purpose. The question of its use for other purposes has not been lost sight of either by the managers or by the Local Goverment Board, and will be again considered as soon as circumstances permit.

Mentally Deficient Prisoners.

Mr. ALDEN asked the Secretary of State for the Home Department whether there were any statistics to show the number of prisoners placed under observation because of their mental condition; what was the policy of the department towards the number who might be classified as irresponsibles; and whether he would be willing to grant a return of such prisoners in all our chief prisons.—Mr. GLADSTONE replied: Both in local and in convict prisons those prisoners who are not certifiably insane but are unfit through mental deficiency for the ordinary penal discipline form a separate class and are specially treated. In the year 1906–07 the numbers were: in local prisons 355 and in convict prisons 107. The policy of the Prison Commissioners is to place these prisoners under the special charge of the medical officers of the prisons and to keep them continuously under the personal care of selected warders. The medical officers regulate their discipline and diet and allow them such employment as is suited to the condition of each individual. In addition to those so classified there are other prisoners temporarily under observation to ascertain their mental state.

Royal Commission on Sewage Disposal.

Mr. MITCHELL-THOMSON asked the Secretary of State for the Home Department when the final or further report of the Royal Commission on the Treatment and Disposal of Sewage, which was appointed in 1898, was expected to be ready.—Mr. JOHN BURNS (who replied) said: I understand that the Royal Commission hopes to issue a further report before the end of the year. I also understand that the investigation of the disposal of trade effluents when not mixed with sewage, which will form the subject of the final report of the Commission, has been commenced.

TUESDAY, JULY 23RD.

Anti-typhoid Inoculations in India and South Africa.

Sir WILLIAM COLLINS asked the Secretary of State for War whether any official statistics existed in regard to anti-typhoid inoculation of British troops serving in India or in South Africa; if so, whether he would lay them upon the table; whether any order had been issued by the Commander-in-Chief in India in reference to anti-typhoid inoculation; and, if so, whether he would state its terms.—Mr. HALDANE replied (by printed answer): A large number of returns relating to anti-typhoid inoculation have recently been received both from India and South Africa and the work of compiling this information in statistical form is at present in progress, but some considerable time must necessarily elapse before the work is completed. Anti typhoid inoculations are being largely carried out in India under the general direction of the Commander-in Chief, but the War Office is not aware of the terms of the specific orders issued by him.

The Plague in India.

Mr. O'GRADY asked the Secretary of State for India whether he wa and indeed any effervescing draught or powder, sold under whatsoever name, or mixed in whatsoever manner.—This is the quibbling clause. An informer comes into your shop, and requests you to make him a dozen soda powders; on your proceeding to stamp them, he objects to it, and begins cursing the Government and stamps altogether, and swears he will not pay threepence for a stamp. I have known an apothecary, ignorant of this quibble, request permission to add a small quantity of magnesia to each powder, supposing this to take off the liability; after a little parleying the informer submits to this, and away he goes and lays an information.

Another quibble is that of *coming into* the shop and requesting you to give him a quantity of carbonated soda and water; when he has stirred a portion of the soda in the water, he asks for a little tartaric acid to make it pleasant. Having drunk this, the villain runs off to the Stamp Office, and swears you have sold him soda water.

There are many other quibbles which the apothecary must be aware of. I caution every one to be extremely watchful, for informers are ever on the alert. A plan for remedying these evils I will submit for your inspection next week, and am, Sir,

Yours truly,
J. F C.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8160 births and 3814 deaths were registered during the week ending July 20th. The annual rate of mortality, which had been equal to 12·5 and 12·3 per 1000 in the two previous weeks, was 12·4 in the week under notice. During the first three weeks of the current quarter the death-rate in these towns, therefore, averaged 12·4 per 1000, the rate *in London* during the same period being 12·0. The lowest rates in the 76 towns last week were 4·5 in Reading, 4·9 in Burton-on-Trent, 5·7 in East Ham, and 5·9 in Willesden; the rates ranged upwards in the other towns to 17·7 in Liverpool, 18·5 in Merthyr Tydfil, 20·1 in Walsall, and 20·1 in Middlesbrough. The 3814 deaths in the 76 towns showed an increase of 40 over the number in the preceding week, and included 397 which were referred to the principal epidemic diseases, against 366 and 341 in the two preceding weeks; of these, 142 resulted from measles, 107 from whooping-cough, 65 from diarrhœa, 33 from scarlet fever, 31 *from* diphtheria, and 19 from "fever" (principally enteric), but not any from small-pox. No death from any of these epidemic diseases was registered last week in Willesden, Halifax, Northampton, Hornsey, Rochdale, York, or in nine other of the 76 towns; the annual death-rates from these diseases, however, ranged upwards to 3·1 in Blackburn, 3·3 in Cardiff, 3·9 in Stockton-on-Tees, 4·1 in Middlesbrough, 5·4 in Derby, and 6·0 in Walsall. *The 142 fatal* cases of measles, were 15 in excess of the number in the previous week; the highest annual death-rates therefrom were 3·1 in Cardiff, 3·9 in Stockton-on-Tees, 4·6 in Derby, and 5·4 in Walsall. The deaths from whooping-cough, which had been 136, 109, and 103 in the three preceding weeks, rose again to 107 last week; the highest rates from this disease were 1·1 in Salford and in Huddersfield, 1·2 in Wigan, and 1·6 in Brighton. The 65 fatal cases of diarrhœa exceeded by 26 the number in the previous week, the highest rates of mortality being 1·2 in Walthamstow, 1·7 in Barrow-in-Furness, and 2·0 in Middlesbrough. Scarlet fever caused a death-rate of 1·5 per 1000 in West Bromwich, and diphtheria a rate of 1·3 in Norwich. There were two deaths from "fever" in London, two in Liverpool, two in Sheffield, and one in each of 13 other towns. No case of small-pox has been under treatment in the Metropolitan Asylums Hospitals for the past ten weeks; the number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had risen from 2658 to 3276 in the ten preceding weeks, had further increased to 3387 at the end of last week; 570 new cases were admitted during the week, against 422, 504, and 493 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 156, 148, and 139 in *the three* preceding weeks, further declined to 126 last week, and were nine below the corrected average number in the corresponding week of the five years 1902–06. The causes of 35, or 0 9 per cent., of the deaths registered in the 76 towns during the week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London, Manchester, Leeds, Bristol, West Ham, and in 50 other of the 76 towns; the proportion of uncertified deaths, however, showed considerable excess in Liverpool, Birmingham, Sheffield, Portsmouth, Rochdale, Grimsby, and Rotherham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had declined from 17·3, to 13·7 per 1000 in the four preceding weeks, rose again to 14·9 in the *week ending* July 20th, and *was* 2·5 *per* 1000 in excess of the mean rate during the same week in the 76 large English towns. The rates in the eight Scotch towns ranged from 9·6 in Aberdeen and 11·2 in Leith, to 17·6 in Dundee and 18·0 in Perth. The 518 deaths in the eight towns showed an increase of 43 over the number in the preceding week, and included 63 which were referred to the principal epidemic diseases, against 59 and 60 in the two previous weeks. These 63 deaths were equal to an annual rate of 1·8 per 1000, which exceeded by 0·5 per 1000 the rate from the principal epidemic diseases in the 76 English towns; they included 23 which were referred to whooping-cough, 19 to diarrhœa, 14 to "fever," and seven to measles, but not any to small-pox, scarlet fever, or diphtheria. The fatal cases of whooping-cough, which had been 18 and 22 in *the two* previous weeks, further rose last week to 23, of which nine occurred in Glasgow, five in Edinburgh, three in Leith, two in Dundee, and two in Paisley. The deaths referred to "fever," which had been 21, 18, and 14 in the three preceding weeks, were again 14 last week, and included seven which were attributed to cerebro-spinal meningitis in Glasgow, three in Edinburgh, and one in Leith. The fatal cases of diarrhœa, which had been 10 and 12 in the two preceding weeks, further rose last week to 19, of which seven occurred in Glasgow, four in Edinburgh, four in Dundee, two in Paisley, and two in Greenock. Of the seven deaths from measles six were returned in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 72, 80, and 68 in the three previous weeks, declined again to 72 in the week under notice, but exceeded by eight the number in the corresponding week of last year. The causes of 24, or 4·7 per cent., of the deaths registered in the eight towns during the week were not certified or not stated; in the 76 English towns the proportion of uncertified deaths did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 19 5, 18·3, and 21·0 per 1000 in the three preceding weeks, further rose to 21·5 per 1000 in the week ending July 20th. During the first three weeks of the current quarter the death-rate has averaged 20·3, the rates during the same period being 12 0 in London and 14·1 in Edinburgh. The 161 deaths of Dublin residents registered during the week under notice showed an increase of four over the number in the previous week, and included five which were referred to the principal epidemic diseases, against 19 and 14 in the two *preceding weeks; of these, four* resulted from whooping-cough and one from "fever," but not any from small-pox, measles, scarlet fever, diphtheria, or diarrhœa. These five deaths were equal to an annual rate of 0·7 per 1000, the rate during the same week from the principal epidemic diseases being 1·5 in London and 1·7 in Edinburgh. The fatal cases of whooping-cough, which had been nine and seven in the two previous weeks, showed a further decline to four last week. The 161 deaths from all causes in Dublin during the week included 32 of children under one year of age and 49 of persons aged upwards of 60 years, each of these numbers showing a further increase upon those returned in recent weeks. Eight inquest cases and seven deaths from violence were registered; and 59, or 36·6 per cent., of the deaths occurred in public institutions. The causes of seven, or 4·3 per cent., of the deaths in Dublin last week were not certified; in London the causes of all the deaths were duly certified; while in Edinburgh the percentage of uncertified deaths was 2·0.

Notes, Short Comments, and Answers to Correspondents.

THE AMERICAN QUACK.

IN our issue of Feb. 3rd, 1906, p. 347, we commented upon the doings and advertisements of the American quack who calls himself C. J. Macaura. His field of action at that time was apparently Bradford and Newcastle-upon-Tyne, but now he seems to have moved to Hull. In the *Hull Mail* of June 18th is a paragraph quoted from the *Bradford Daily Argus*. It is headed in the usual deceptive way of quacks who quote the names of electrical experts to further their own ends, "Remarkable Statement by Edison." The statement attributed to Edison is as follows: "It is my firm belief that if electricity was thoroughly understood by the medical profession and scientifically applied, humanity would be the gainer to such an extent that the old system of drugging would soon be forgotten." The rest of the article is mainly devoted to saying that "Dr. Macaura" does understand electricity and can apply it scientifically, with, of course, the usual amazing cures. Internal evidence seems to show that the paragraph was written by Macaura himself, for we read, "We have right here in Hull many striking examples ......" How any respectable newspaper can be a party to inserting such matter we cannot understand.

A PLEA FOR VENESECTION.

To the Editors of THE LANCET.

SIRS,—It is always unwise to criticise the treatment of a case you have not seen, so that I will not follow "G.P.'s" example (THE LANCET, July 20th, p. 204) in referring to the recent sudden death in the House of Commons except as a peg on which to hang some remarks on venesection. A case which I saw in consultation with Dr. J. Russell Ryan and Mr. G. R. Radmore last October well illustrates the excellent result which often attends upon a timely venesection. The patient was a fat, flabby lady, aged 64 years. The history I obtained was that except for some mental excitement she was in her usual health in the morning. About noon she was seized with right-sided twitching and an hour later she became unconscious. When we met in consultation at 2.30 P.M. the patient was comatose, with conjugate lateral deviation of the eyeballs and right-sided convulsive movements. Her face was cyanosed. I at once advised venesection and she was bled to ten ounces. Even while the blood was running the movements abated and soon afterwards ceased and the cyanosis disappeared. The patient gradually regained consciousness and in the course of a week or ten days she was much in her usual condition physically, though mentally she remained rather feeble. I think that this was certainly a case in which life was saved by venesection. In these cerebral cases much depends on the promptness of the withdrawal of the blood; if there be delay irretrievable damage may be done. In a case which I saw earlier in the autumn the patient, a man, aged 65 years, after having been comatose for 48 hours regained consciousness as soon as he was bled and lived for two or three months, dying eventually from uræmia. So that though early venesection should be the rule there are cases in which it does good, even though the patient has been unconscious for many hours.

It is to be hoped that the present generation of medical men will estimate at its true value a method of treatment which was much abused at one time but which fell into undeserved neglect.

I am, Sirs, yours faithfully,

July 22nd, 1907. F. DE HAVILLAND HALL.

NOISY STREETS AND HOUSE PROPERTY IN LONDON.

AT a meeting of the Street Noise Abatement Committee on July 20th it was stated that the motor-omnibus and traction-engine traffic had, in the course of two years, depreciated the value of house property in London to the extent of fully £6,000,000, whilst every week of the existing state of things was adding thousands of pounds to the loss that was being incurred by property owners.

TRUE CLEANLINESS.

To the Editors of THE LANCET.

SIRS,—One fertile source of contempt in the Anglo-Indian for the Indian native is the absence of the pocket-handkerchief as an intermediary in the blowing of native noses. The native retorts that his practice is far cleaner than that of the northern European who puts a quantity of uncleanly stuff—most likely full of disease germs, one may conclude—to ferment in a hot, steamy breast pocket. Just the same contempt is felt for the same reason by the north Italians for the south Italians—in particular for the Neapolitans. This race, being quick and intelligent, long before official science, discovered the infectiousness of tuberculosis; in fact, *crede experto*, a person with a mere bronchial catarrh, unless he conceal it, cannot hire a room for love or money among the peasantry round about Naples. How can we fail to correlate these facts and infer, unless science disprove it by actual observation, that the wipe, now also universal among the masses who do not scent it as a rule, is a source of consumption, catarrh, &c., among them? Pocket-handkerchiefs are also not made use of by the Chinese, who, as regards personal cleanliness, from lowest to the highest—as, e.g., in brushing the teeth, using toothpicks, cleansing the mouth and hands before and after meals, and a number of other things—are much more particular than the bulk of our people. In their case the short open nose, and absence of hair upon the face, render the practice comparatively unobjectionable, but it would not be tolerated amongst a highly refined people like the English, with long noses, an intolerable amount of thick fur about the face, and a climate which develops an excessive amount of nasal mucus.

The only prophylactic that one can suggest is some good antiseptic scent, to be used on the pocket-handkerchief even more scrupulously by the plebeian of the slum than by the peer.

I am, Sirs, yours faithfully,

W. W. STRICKLAND, B.A. Trin. Coll., Cambridge.

Singapore, June 21st, 1907.

AUGUST BANK HOLIDAY ON THE CONTINENT.

TICKETS at reduced fares available for eight days will be issued by the Great Eastern Railway to Brussels, July 31st, August 1st, 2nd, 3rd, and 5th, and to Zürich, viâ Harwich and Antwerp. For visiting the Hague, Scheveningen (the Dutch Brighton), and Amsterdam for the dead cities of the Zuyder Zee, special facilities are offered viâ the Company's British Royal Mail Harwich–Hook of Holland route. For the convenience of passengers tickets dated in advance can be obtained at the Liverpool-street Station Continental Inquiry and Booking Offices.

A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—I crave the courtesy of your columns to warn medical men against one who is obtaining access to their hospitality and assistance by pretending that he is sent to them by me. The man is question (aged about 40, dressed as a ship's surgeon) does not deserve the charity he claims. I am, Sirs, yours faithfully,

ARTHUR KEITH, M.D. Aberd.

London Hospital Medical College, July 22nd, 1907.

◆

Alpha.—The figures refer, no doubt, to some form used in the institution for purposes of registration. They may indicate the character of the neuritis, but that depends upon the method of registration adopted by the hospital. There is no form of registration common to all such institutions. We have not the slightest idea what the figures mean nor is the board in question intended to convey either to the patient or to his friends the nature of his disease. The board is for the use of the hospital authorities and their staff.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

Ormond-street (2.30 P.M.), Tottenham (Gynæcological, 2.30 P.M.).

whether these and "other similar incidents of athletic competition" justify us in concluding that there is "a falling off in the physical energy of the nation." Why, you ask, should not others learn to play as well as, or better than, ourselves the games we have invented? Speaking generally, there is, indeed, no reason why they should not. By the law of averages we must expect to suffer our due share of defeats. If, however, these are greatly in excess of what can be accounted for by the law of averages clearly some disturbing factor or factors must be in operation.

Viewed thus, I find nothing remarkable in the recent victory of the Belgians, or of M. Massey, or Mr. Gould, or even of Mr. Brookes. Such successes are sufficiently explicable by the law of averages. The successes of the colonials in football and cricket strike me, on the other hand, as very remarkable, inasmuch as they are far in excess of what by the law of averages we should expect. The colonial record in the sphere of football and cricket is, indeed, phenomenal. Putting aside the extraordinary feats of the Australian cricketers who are drawn from a population of less than 4,000,000, let us consider the recent records of the New *Zealanders and South Africans in football* and cricket. Although the population of New Zealand is considerably under 1,000,000, while that of England is upwards of 32,000,000, the New Zealanders had no difficulty in defeating here in England every 15, including an all-England team, which we opposed to them. The South Africans, again, representing a population of less than 750,000, had an equally brilliant record. In each case the colonial successes were due to consistent all-round merit—to a combination of skill, dash, and endurance. Not only did the best teams we could put in the field go down before our adversaries, but the representative teams of the ancient universities, containing the flower of our English youth, were altogether outplayed by them. It has long been our proud boast that our battles have been won in the playgrounds of our public schools, the inference being that all the qualities which make for virility are cultivated there, but seeing that our ancient universities are fed mainly from the public schools it looks very much as though these latter were turning out a less virile stuff than that furnished by the colonies.

Excellence in a game such as Rugby football demands a certain toughness of fibre, and it is perhaps largely for this reason that the Welsh teams, composed as they mainly are of men who live by physical labour, were so much more successful against the colonials than the English teams, which are drawn chiefly from the upper middle class, reared under conditions which, as it seems to me, make for "softness." In this connexion the superiority of the golf and cricket professionals over the amateurs is of interest. Amateur golfers and first-rate amateur cricketers are drawn almost entirely *from* the upper middle class, while the professionals, both in golf and cricket, are, I understand, derived for the most part from the so-called "working" classes. Now can we wholly explain the superiority of the latter on the assumption that they devote more time and care to the game which they have made a profession than the amateurs who indulge in it as a pastime only? This is at least doubtful. As regards golf, e.g., the amateur players in England are much more numerous than the *professionals*. Many of them, moreover, begin to play when quite young and devote quite as much time to the game as the professionals. How comes it, *then*, that the latter show a consistent superiority over the former? I suggest that it is partly due to the possession of greater staying power and partly to a richer *endowment of* "nerve," or shall we call it imperturbability?

Both these qualities have been conspicuous in the South African cricketers, whose recent successes in this country are perhaps even more remarkable than their brilliant achievements in the football field. Think of it. A colonial community of less than 750,000 sends to us, with our population of upwards of 32,000,000, a *team* to compete in our national game—our most typically national game—cricket, and displays not only a decided superiority over our county teams, but bids fair to hold its own against a representative English *eleven* chosen from both professionals and amateurs. There is, perhaps, no game which makes greater demands on what may be termed manly excellence than cricket, requiring as it does not only *muscularity*, agility, and endurance, but judgment, decision, patience, good temper, unselfishness, and "nerve." No one, indeed, who does not exhibit the best qualities of manliness is likely to make a good cricketer. All these qualities our brothers from over the seas have displayed in a remarkable degree, and it seems difficult to avoid the conclusion that the conditions under which they live are more favourable *for* the development *of* some of them, especially perhaps of endurance and nerve, than the conditions obtaining in this country. They seem in Greater Britain to be breeding a hardier and more virile race than in *the mother country, and it is probable that, given equal* opportunity, the same superiority which the Australasians and South Africans have displayed in cricket and football would be equally manifest in tennis, polo, and other games of the kind.

I am, Sirs, yours faithfully,

Wimpole-street, W., July 21st, 1907. HARRY CAMPBELL.

PS.—I see in this morning's paper (July 22nd) under the heading "A Trial of Nerve" that the King's Prize has been won by an Australian. This, coming on top of Mr. Brookes's *successes, is noteworthy.*

THE CORNEAL REFLEX IN ANÆSTHESIA.

To the Editors of THE LANCET.

SIRS,—In the issue of THE LANCET of July 20th, 1907, on p. 141, occurs a sentence which involves a change of view of the most vital and lasting importance. In the course of a lecture on General Surgical Anæsthesia Dr. F. W. Hewitt thus expresses his carefully considered opinion with regard to the clinical signs when using chloroform or a chloroform mixture. "Provided that the respiration be freely proceeding and *that the corneal reflex be present* even to a slight degree, the patient's general *condition* at the *moment* of observation may be regarded as satisfactory." In the edition of his work on "Anæsthetics and their Administration," published in 1901, Dr. Hewitt said, referring to chloroform, p. 336, "The lid-reflex should, as a general rule, be absent ...... the third degree of anæsthesia cannot, generally speaking, be said to be present when this phenomenon can be elicited," and again on p. 363, "In many cases a trace of this reflex may be permitted but there are numerous subjects and numerous operations in which both corneæ must be kept absolutely insensitive throughout."

Dr. Hewitt's latest opinion coincides with the view which I ventured to record in the *British Medical Journal* on Feb. 4th, 1905, in these words, p. 245: "Never completely abolish the corneal reflex. The corneal reflex, which is produced by touching the centre of the patient's cornea and both watching and feeling the responsive closure of the upper eyelid, is one of the last primary reflex actions to become paralysed. When this has been abolished the fourth stage of dangerous anæsthesia has been entered."

I do not say that it is possible always to avoid the momentary disappearance of the corneal reflex, but that the third stage or that of surgical anæsthesia is limited, and should be taught as being limited, by the abolition of the corneal reflex in both eyes. Differences of opinion which may be expressed with regard to this conviction are more likely to depend upon imperfect methods of eliciting this reflex than upon disbelief in its truth, the accuracy of which is founded upon continual daily observation.

I am, *Sirs, yours faithfully,*

Harley-street, W., July 23rd, 1907. H. BELLAMY GARDNER.

THE INTRODUCTION OF THE METRIC SYSTEM INTO PHARMACY.

To the Editors of THE LANCET.

SIRS,—Several circumstances indicate that the time has come for introducing metric weights and measures into the medical practice of this country. That system became legal in Great Britain a few years ago and no other is now permitted in the pharmacopœias of any civilised country except Great Britain which, however, has begun to print the new and old side by side.

The disciplinary and regulating body of the British medical profession, that is to say, the General Medical Council, has recently gone further than the Pharmacopœia by recommending, after a unanimous vote, that the metric system be made compulsory by law for everybody in all bargains and sales where weight or measure is specified. A Parliamentary majority of two to one was pledged in writing to support a Bill to this effect, but it was defeated by 150 to 118 votes, mainly through opposition from the textile trades, which

Communications, Letters, &c., have been received from—

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (*to ensure insertion the same week*) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; *copies only* should be forwarded.

Cheque and Post Office Orders (crossed "*London and Westminster Bank, Westminster Branch*") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or *Subscriptions should be addressed.*

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France.—J. ASTIER 31, Rue Bapts, Asnières, Paris.

here. There is also some display of hats, old and new, and notably the very tall silk hat worn by O'Connell in 1840; but no one has attempted to solve the problem of ventilating these very uncomfortable and heavy forms of headgear.

On the right of the Central Palace there is an oblong building called the Palace of Industries, and here, among other things, is the New Zealand section. Both here and in the very elaborate and special pavilion built for the Canadian exhibits the first impression is that these colonies are doing just what should be done with special success in Ireland itself. Both exhibits have refrigerators and through the glass panes can be seen the fresh butter, the poultry, and the frozen meat. So much butter is there from Canada that it has been moulded to represent a Canadian farm, the chickens made of butter that play about in the foreground being life size. Then there are pyramids of cheese; in fact, the very things that could be most abundantly produced in Ireland itself. There is a small working model of a section of the R.M.S. *Papanui* in the New Zealand section. This shows how thousands of carcasses of sheep can be laid in the hold of the ship and how the fans propel cold air over them, so that they are preserved during the long journey to England, and the machine lifts to bring them up to the landing stage with the minimum of effort. All this is interesting as indicating the increased sources of food-supply so essential to the health of the community. There is also a considerable collection of mineral waters from New Zealand. Many of the springs known to exist have not yet been analysed. Others have been carefully examined and placed forthwith under Government control. These springs and baths are entrusted to the supervision of Dr. Arthur S. Wohlmann who represents the Government. Some of these are alkaline sulphur, bathing and drinking waters, and are credited with having effected numerous cures, not only of the inhabitants of New Zealand but of patients arriving from distant parts. There are also blankets, cloth, and rugs made in New Zealand. Some of the woollen rugs are especially fine, with beautiful colours, designs, and finish. As non-conductors of heat, cold, or electricity, such woollens are especially useful to invalids. Close by the New Zealand section is the curious exhibit of Lovibond's patent tintometer, an instrument and system of developing and noting the quality of colour. This method of analysing, accurately measuring, and recording the density, shade, and colour is applied not only to numerous industrial purposes but to the blood of man and animals and is therefore occasionally of use in the diagnosis of disease. In conversation with Mr. Lovibond I elicited a curious piece of information. In his process a great number of small glass slides are employed and these are tinted various shades of red, blue, and yellow. Seven young women are engaged at this work; and in the course of years some 30 to 40 women have been so employed. The preparation of these pieces of glass is identical whatever the colour, yet those who work with the red glass are very soon tired and exhausted. This is so well recognised a fact that no one is allowed to work with the red colour for a long time. Near at hand there is a large model of one of the Gilbey vineyards in the Bordeaux district with two fine white bullocks dragging a cart loaded with grapes. The Irish profess to be connoisseurs of claret. They say that their climate favours the maturing of such wine and maintain that Napoleon himself was supplied with claret from a Dublin cellar. In any case, Messrs. W. and A. Gilbey are making good use of the publicity which the exhibition gives to popularise in Ireland the use of wholesome cheap clarets which are certainly very preferable to the questionable spirits sold too often under the name of whisky.

There is besides a small French section where the wine-growers of France exhibit samples; there are also cognacs, liqueurs, and champagne in this section. The Vichy waters and salts have a large case and there is a collective pharmacy exhibit where some of the best known wholesale druggists have sent many of their products. Then Dr. Madeuf, who has never been known to miss an opportunity of bringing forward the claims of his League for the Prevention of Sea Sickness, is here with a big display of literature on this subject. In this section there are also catguts for ligatures, &c., produced by the very ingenious Triollet process which insures sterilisation without destroying the flexibility or suppleness of the catgut or hindering its ready absorption.

In the gardens there are several small structures, one specially devoted to Lemco and Oxo and another to Chivers's jellies and jams. Then there is a pavilion for "Working Exhibits," where men and women are at work making cloth, carpets, lace, boots, gloves, &c. Most of these are home industries, the sort of work that can be done in a cottage, and on the walls there are photographs of workers on the continent similarly employed. Thus we see shirt-makers and boot-makers in France stated to be earning from 2 to 3 francs per day, and glove-makers only 1.50 francs. They all look very tidy and evidently impressed with the fact that they were being photographed. The Belgian workers make a more general use of aprons and therefore look even more tidy. Only one of these photographs is realistic, and that is of a German corset-maker who earns one mark per day. Here, in the crowded little room, the corset trimmings are spread over slop-pails and washing-basins, and this does convey some idea of the dangers to health caused by the home work and sweating systems. Otherwise these photographs—as, indeed, the whole of this sort of exhibits—convey very false impressions and can best be compared to the happy and picturesque peasants who sing in the chorus of an operatic scene.

Next to this pavilion comes a model village hall which is perhaps more satisfactory than its neighbour the model village hospital. Not so much is needed in a hall only occasionally occupied to the full. The hall of wood and corrugated iron seems ably contrived and a fair provision is made for ventilation. But the idea of a hospital made of wood and iron is not so happy. On entering to the right there are a small nurses' sitting-room and pharmacy. Here on the walls are hung proclamations issued by the National Association for the Prevention of Tuberculosis. On the other side of the entrance is a small nurses' bedroom, with just one chair, a washstand, a chest of drawers, and a camp bed. Next to this is a small operating-room, with only one small window and wooden walls. Yet to judge by the operating table and instruments supplied by Messrs. Fannin and Co. of Dublin it seems intended that major operations should be performed here. In the back part of the cottage there is a small service bedroom giving on to a fairly large kitchen, with a scullery and pantry beyond. Finally, in a sort of passage there are two closets, a bathroom, and a nurses' sink. So much for the services. As for the patients there are only two rooms available for them and these are so small that they can only hold two patients each. To build a hospital, even be it but a cottage hospital for only four patients, is certainly a difficult matter.

Opposite there is a cottage made of hollow concrete blocks. The "Pioneer" machine produces these blocks, and they resist fire, are durable, and can easily be moulded into very artistic designs. By the side of this there is another cottage, with living room and three small bedrooms, which can be built for £135. Such extreme cheapness should not be necessary and in any case sufficient space cannot be obtained at the price.

The largest building of the exhibition is undoubtedly the spacious gallery called the Palace of the Mechanical Arts. Here there are some large machinery and some exhibits that would interest hygienists, such as E. Green and Son's Economiser Works of Wakefield as a contribution to the problem of warming buildings; Shanks and Co.'s porcelain baths and sanitary hardware; and the immense exhibits of the Carron Company with numerous firegrates, kitcheners, baths, &c. Opposite this are the exhibits of the great liners of the Cunard, the White Star, the Booth, and other popular passenger companies. The problem of ocean travelling is a fascinating one to all who have practical experience of its intricacies and the beautiful models shown here facilitate its study. The models of the most recently constructed ships can be examined here, such as the huge 32,000 ton Cunarders and the new Booth Line ship *Lanfranc*. The latter takes health-seekers to the winter resorts which the Portuguese are endeavouring to develop.

In the machine gallery and in various parts of the exhibition there is a considerable assortment of the machinery and numerous appliances that are employed in creameries and dairy farms generally. This, it need hardly be said, is a matter of great importance to a country like Ireland which should produce an enormous amount of milk, butter, and cheese. His Majesty King Edward VII. has this week visited all these exhibits. His presence and the immense enthusiasm of the reception given should help the cause that the Dublin exhibition is meant to promote—namely, the development of industry and technical knowledge in Ireland.

authorities on the health of public schools. There every new boy undergoes a carefully recorded and rather full physical examination and the games and exercises that he "may play" and "ought to be made to play" are also recorded. But we must go further than this system of games. I quite agree that every boy in every school ought to have a course of physical exercises prescribed for him, adapted to his particular need, and that he should not be allowed to play any game unless he has attained a certain level of muscular development; then we should have a very different condition of affairs from that just revealed. In a public school it would be a point of honour to reach the necessary degree of muscular development to play games, and in the elementary schools the physical exercise would itself develop the muscular tone which is wanted. I would urge on the educational authorities that they are responsible for the development of the pupils' bodies as well as their minds and that it is of little use to the nation to bring up men with their minds stored with facts but their bodies left ill-developed and generally degenerate. Playgrounds are as necessary for the healthy development of our children as school buildings, gymnasia as class rooms, trainers in physical exercises as school teachers, and if every board school cannot be provided with these necessary adjuncts they should, at all events, be provided in certain areas, so that physical development is provided for and insisted on for all children. Games are, of course, most valuable for those who play them, but there is no muscular activity in watching others play them; moreover, few games bring into action the whole of the muscular system with the same completeness as does a properly devised system of physical exercises. Games, too, are impossible in many cases for the pupils in the elementary schools in large cities, whereas physical exercises take up little room and there are few places in which arrangements might not be made for carrying them out in connexion with the existing schools, to the great and lasting benefit of the individual child and of the nation at large. We may see the great value of gymnastics, games, and physical exercises by following the history of Japan during her recent development. I will quote this history to you from a lecture recently delivered under the auspices of the University of London by Baron Kikuchi, one of Japan's experts in education.

[Dr. Davy next referred to the example of the Japanese who, when they emerged from feudalism, found that the physical training of the young began to be neglected and therefore established Government training in physical exercise, gymnastics now being taught in every school for from three to six hours per week. Of equal importance with physical culture (which should by no means be left in entirely unprofessional hands), continued Dr. Davy, comes the question of the feeding of the people and this question, with its bearing upon infant mortality, has a great influence upon the health of the nation. He continued:—]

I know of nothing more worthy of the attention of this great Association and of its powerful organ in the press than that duty of pressing on the statesmen of the day the need for making elementary physiology and hygiene a compulsory part of the education of all the children in this country. We shall never be able to deal satisfactorily with physical degeneracy and the prevention of disease so long as the majority of the men and women in the nation remain in absolute ignorance of the very rudiments of science and hygiene. It is not creditable to our educational systems that a so-called "well-educated" gentleman, who may one day be called on to legislate for his country in Parliament, should be able to go through one of our best public schools and take a degree at one of our oldest universities without the least knowledge of the composition of the atmosphere and without the most elementary ideas as to food and hygiene; but so it is, and I despair of improving the health of this country and of preventing a mass of preventable disease so long as this anomalous condition of education exists. For in the prevention of disease we as a profession can do little or nothing unless we have the support of public opinion behind us to assist in carrying out the precautions which science shows to be necessary. It is, I think, greatly to our credit that we have accomplished as much as we have in diminishing disease under the present condition of affairs; that we can do little or no more until public opinion is aroused in the matter I will illustrate by asking you to consider the history of pyæmia, typhoid fever, and tuberculosis. These three diseases have been proved to be caused by the development of certain micro-parasites which have all been discovered within the last 30 years. Pyæmia and typhoid fever are, as you know, in the category of diseases which come under the supervision of the Act which deals with infectious diseases, while tuberculosis is not; so that in the latter case we have no means of enforcing the precautions which we know to be necessary.

Now, in the case of pyæmia, the magnificent work done by Lord Lister has shown the world not only the cause of this disease but the actual precautions by which it may be prevented, the use of these precautions depending on the surgeon and his assistants and on no one else. And so well are these precautions carried out that pyæmia has become almost extinct within these past ten years throughout the civilised world, with a saving of life and misery which cannot be calculated. Typhoid fever is also becoming more and more infrequent, and this is generally credited entirely to the improved sanitation and better water-supply of the country. But I think these are by no means the chief factors in the case, for there are plenty of insanitary houses still remaining in England and the water-supply is too often open to the gravest suspicion. The decline of typhoid fever is largely due to the fact that medical men have done much to destroy it. Its bacilli nowadays are never allowed a chance, at any rate in this county. In every case of the slightest doubt, days before there is any possibility of making a certain diagnosis of typhoid fever, it is the invariable practice thoroughly to disinfect the patient's stools; and it is to this constant and systematic destruction of its bacteria by disinfectants that, I believe, the diminution of typhoid fever is chiefly due; and that if these measures of disinfection are continually carried out this disease will in a few years be as rare as its kindred disease, pyæmia. How greatly it has disappeared in this neighbourhood and with what loss to our profession may be gauged by the following facts. My immediate predecessor in practice told me that 50 years ago he frequently made £300 a year from patients suffering from this disease. I can tell you that for the past 15 years I have not taken £50 a year from this source and that during the past few years my income from typhoid fever has hardly averaged five guineas a year.

Far different is the history when we come to examine tuberculosis, the exact nature of which as an infectious parasitic disease was discovered by Koch 25 years ago. Now at the onset I know that there are still a few members of our profession who do not like to class it with the other infectious diseases, fearing that the effect of so describing it will bring great hardship on the consumptives in England. I admit that under ordinary conditions the consumptive is not infectious to other people coming merely in contact with him, and that if he will take the necessary precautions with his sputum he may not be infectious to anyone. We all, too, recognise that he is not infectious unless his sputum contains the tubercle bacilli, and that that is often not present, if at all, until very late in the disease. But, nevertheless, consumption is an infectious disease in precisely the same manner as is typhoid fever. In the one you have the bacilli of infection in the sputum and in the other in the motions, and unless you disinfect them both the infection becomes generally distributed.

Now compare the history of tuberculosis with those of typhoid fever and pyæmia. I am quite aware that it has decreased under the influence of improved sanitation during the past few years, but yet its prevalence is even now appalling. Approximately, its death-roll in Great Britain is 60,000 persons a year; and Dr. R. W. Philip of Edinburgh has shown that the ascertained mortality from consumption may be safely multiplied by ten in order to represent approximately the number of persons living and already seriously affected at the time, so that Great Britain at the present moment contains 600,000 poor patients with a preventable infectious disease, the large majority of whom are bound slowly to die from an illness which will linger on for from two to five years. And worse than all this during a considerable part of this long illness (in the case of the majority of poor patients at any rate) no real effort is made to prevent them from infecting their families or those with whom they come in contact while at work; so that a constant infection is going on of persons around them, and the toll of the death-roll is continuously kept up. I think it is time that we spoke out the truth about this disease with no uncertain voice; for surely it is time that something was done officially in this matter, and that the attempt to stay the ravages of this terrible disease be no longer

October. The terms of the ordinance have been already given in The Lancet, but their general tenour may be again outlined. The winter session is to be divided into two half-sessions, lasting respectively from October to Christmas and from January to March, and examinations are to be held at the end of the first half session as well as at the end of the second half and of the summer session as heretofore. Further, the examination in physiology may be taken at the end of the second winter and that in anatomy three months earlier than formerly. The subjects of the final examination may be taken separately. Thus, forensic medicine and public health may be taken at the end of the summer after the fourth winter, midwifery at the Christmas of the fifth winter, systematic medicine and surgery at the end of the fifth winter, and clinical medicine and surgery in the summer thereafter. The subjects of materia medica and pathology have changed places. The feeling that these changes were highly desirable is practically unanimous and it is felt that they will relieve students and examiners alike and will tend to raise the standard of work. It would be interesting to know what influences were at work to remove the opposition of Glasgow and Aberdeen to these alterations. It is the first step towards the autonomy which Edinburgh feels is so necessary if education is to be kept abreast of the rapid changes which are taking place in knowledge and in the methods of instruction. The University is to be congratulated warmly on the success of this forward movement.

The Royal Society of Edinburgh.

At a meeting of the Royal Society of Edinburgh held last week the Keith prize was awarded to Thomas H. Bryce, M.A., M.D. Edin., for his two papers on the Histology of the Blood of the Larva of Lepidosiren Paradoxa.

Compliment to Sir A. R. Simpson, M.D. Edin., &c.

It was intimated in The Lancet some time ago that a fund was being raised to commemorate in some way the long services which Sir A. R. Simpson had rendered to medicine in Edinburgh. It was decided that the money should be applied to the endowment of a bed in the Royal Maternity and Simpson Memorial Hospital. On July 15th the sum was formally handed over to the board of directors.

Medical Journalism in Scotland.

It is understood that steps are being taken with a view to see whether it would not be possible to combine into one the medical journals published in Scotland. Whether the time is ripe for such an amalgamation remains, of course, to be seen and such an amalgamation has both advantages and disadvantages.

The Glasgow Maternity Hospital.

In issuing their seventy-second report the directors of this hospital have made a special appeal on behalf of the new building fund. An interesting survey is given of the history of the hospital. It was originally started in the grammar school wynd in 1834. In 1841 it was removed to a small house in St. Andrew's-square. Here for 19 years it did much to alleviate suffering among the poor and as a teaching school. In 1860 the hospital had outgrown its St. Andrew's-square premises and after careful consideration as regards the most suitable situation a house in Rotten-row was purchased and served for 20 years to carry on the work. In time, however, this house became too small for the demands made upon it, and in 1880 the directors built on the same site the present hospital. Now in turn this building is proving too small for the amount of work that has to be undertaken. A glance at the numbers of patients in the different years gives an idea of how the work has increased. In 1860 the number of women taking advantage of the hospital in its in-door and out-door departments was 944, in 1880 it was 1288, and in 1906 it was 3687. In order to meet the pressure on their present inadequate space the directors have acquired the properties on the three sides of Ure-place, and here it is intended to erect buildings with accommodation sufficient for the patients and at the same time suitable for the teaching of practical obstetrics and gynæcology. The sum which the directors require is £80,000 The price of the ground is £15,000, for the new buildings £15,000, and for furnishings, &c., £5000.

University of Aberdeen: Appointment of Examiners.

At a meeting of the Aberdeen University Court held recently the following appointments to examinerships were made:—Geology: Mr. A. Morley Davies, D.Sc., lecturer on Palæontology, Birkbeck College, London. Mathematics and Natural Philosophy: Sir W. D. Niven, K.C.B., M.A., LL.D., late Director of Studies, R.N. Medicine: Mr. Robert A. Fleming, M.A., M.D. Edin., lecturer on the practice of medicine in the School of Medicine of the Royal Colleges, Edinburgh. Midwifery: Mr. Alexander W. Russell, M.A., M.D. Aberd., assistant physician to the Glasgow Maternity Hospital. Zoology: Miss Marion J. Newbigin, D.Sc., lecturer on zoology in the Medical College for Women, Edinburgh. For the Diploma in Public Health: Mr. J. Taylor Grant, B.Sc., M.D. Edin., lecturer on medical bacteriology, Medical College for Women, Edinburgh.—The summer session at the University closed on Friday, July 12th.

Aberdeen City Lunacy Board.

The Aberdeen city district lunacy board has decided that the rate to be charged in the Kingseat Asylum for patients belonging to other parishes should be £35 per annum for the year ending May 15th, 1908. The asylum committee of the board reports the receipt of seven offers to cover the whole of the legal liability of the district board under the Workmen's Compensation Acts, 1897 and 1906, the Employers' Liability Act, 1880, and at common law, for the asylum officials and servants at a total premium of £21 5*s*., subject to a discount of 15 per cent. for agent's fees; and there was also laid on the table an offer from the General Accident Insurance Company to cover the same risk at a net premium of £8 18*s*. 9*d*., the whole of the offers being subject to wages adjustment at the end of the year. The committee unanimously recommends the acceptance of the offer by the General Accident Insurance Company.

The late Mr. David Johnston, L.R.C.P. Edin.

Intimation has been received in Aberdeen of the death, at 55, Kentish Town-road, London, of Mr. David Johnston, L.F.P.S. Glasg., who at one time carried on an extensive practice in Aberdeen. Mr. Johnston was a native of Glasgow. He acted for a time as a clerk in the office of the City of Glasgow Friendly Society and later was appointed agent to the Aberdeen branch. Two years after this Mr. Johnston commenced to study medicine. After qualifying he commenced practice in Aberdeen in 1870, and soon became very popular. In 1877 he disposed of his practice and became connected with the management of the Heathcot Hydropathic Institution. He afterwards resumed medical practice in Aberdeen and followed his profession for a number of years. He entered the town council in 1871 as a representative of the first ward and served for five years. Leaving Aberdeen about 25 years ago Mr. Johnston went to England and eventually found his way to London where he died at the age of 73 years. He was twice married and leaves two sons and one daughter. While attending a patient he fainted and two days later passed away. The deceased gentleman was a keen temperance reformer.

July 23rd.

IRELAND.

(From our own Correspondents.)

The Belfast Health Commission.

On July 16th Mr. Cutler, the city surveyor, was examined before the Commission. He said that the Act of 1899 bound the corporation to carry out a satisfactory purification of the sewage discharged into Belfast Lough within three years and that these three years had expired before he was appointed. In about three months he proposed to bring forward a scheme and he thought that within 12 months he could put in enough sprinkling beds to treat the normal outflow. Mr. J. C. Bretland, who was city surveyor from 1884 until 1903, said with regard to the size of the sewers in Belfast that he had followed the advice of a distinguished consulting engineer. Dr. E. A. Letts, professor of chemistry, Queen's College, Belfast, gave evidence in reference to experiments carried out by him regarding the discharge of sewage into the Lough. Mr. R. Meyer, chief clerk to the corporation, said that in 1900 the corporation applied for a loan of £78,000 for the purpose of enabling it to construct purification works, but the Local Government Board would only sanction £50,000, as it was of opinion that while the general lines on which it was proposed to treat the sewage before it was discharged were satisfactory it was desirable that a greater degree of article of food influences chronic osteo-arthritis. Have we in some of our statements about the harmfulness of particular foods advanced beyond Ibn Haukal, who, in about A.D. 950, describing the inhabitants of Palermo, said: "Their evil habit of eating raw onions in excess; for there is not a person among them, high or low, who does not eat them in his house daily, both in the morning and evening. This is what has ruined their intelligence, and affected their brains, and degraded their senses, and distracted their faculties, and crushed their spirits, and spoiled their complexions, and so altogether changed their temperament that everything, or almost everything, appears to them quite different from what it is." I strongly suspect that in those days onions were a cause of irregular gout.

For many years disordered action of the liver has been invoked to explain certain forms of indigestion known as hepatic dyspepsia. Here, too, medical men have sinned so often that a very favourite diagnosis with the laity is "liver out of order." This is a bad instance of our accepting an explanation which has nothing to support it instead of saying we do not know. The liver may be almost destroyed by new growth or abscess and yet none of these symptoms arise, they have never been produced experimentally as a result of interference with the liver, there is no constant appearance in the liver after death when these symptoms have been present during life, and it has been shown that the so-called cholagogue drugs which experience has taught us benefit these symptoms have no effect on the secretion of bile. In spite of these facts the diagnosis of hepatic dyspepsia has been made, I will undertake to say, many times this day. Everyone who makes it, instead of confessing that he does not know the cause of the symptoms, shuts out from his mind all thoughts as to what can be the correct interpretation of these symptoms and so perhaps retards the progress of knowledge.

A few generations ago physicians taught that blood might come from the gastric mucous membrane, although after death no source for the bleeding could be found. This they attributed to vicarious menstruation, but when it was shown that this interpretation was incorrect the medical profession was not content to say it did not know the cause of the hæmatemesis but said, "Let us suppose it is due to a gastric ulcer"; and accordingly it was stated that gastric ulcer was much commoner in women than in men, and whenever a young woman vomited blood she was, unless some other obvious cause for the hæmatemesis was apparent, said to be suffering from a gastric ulcer. I am sure it will be conceded that many young women have been said to have an ulcer of the stomach solely because they had hæmatemesis. A consideration of the experience gained in the post-mortem room would have shown that morbid anatomy reveals no such excess of gastric ulcers in women as we should have expected if all the cases of hæmatemesis in women were due to an ulcer; and now we know from knowledge derived from the deadhouse, and also from that acquired by seeing the stomach opened during life, that there is a condition, to which the term "gastrostaxis" has been applied, in which blood oozes from the gastric mucous membrane without ulceration, and that this is commoner in women than in men. So simply because instead of saying they did not know and diligently studying these cases in the post-mortem room physicians hastily concluded that they were all examples of gastric ulcer, hundreds of young women have been put through the irksome and deleterious treatment of prolonged rectal feeding for an ulcer which they have not had, and our knowledge of gastrostaxis has been kept back many years.

Sometimes, as we have already seen, when speaking of irregular gout, we attempt to pacify this dislike to acknowledge that we do not know by words which do not really help us at all; in fact, by lulling us into the belief that they explain facts when they do not they lead us to imagine that our knowledge has rock for its foundation when in truth it is built upon sand. For example, a teacher tells his students that alcohol is the cause of the peripheral neuritis from which the woman before him is suffering, but in saying this he fails to explain the remarkable facts that the disease is commoner in women than in men and picks out the anterior tibial nerves before any others. There must be something different in the nerves of women from those of men and of the nerves in women the anterior tibials must be different from the others. Now is the opportunity for the soothing influence of words; instead of being helped to face these facts as inexplicable in the present state of our knowledge we are told that alcohol has a selective action upon these nerves, especially in women, just as lead is said to have a selective influence on the musculo-spiral nerves. But does this help us? Surely not; it merely restates the fact that is evident to everybody; it is no explanation but only an attempt to befog us with words and so possibly to retard the true explanation. Then, further, when reflecting upon the way in which alcohol causes disease we must remember that no explanation is entirely satisfactory which does not explain how it is that some patients—noticeably a few children—have cirrhosis of the liver indistinguishable from that ascribed to alcohol and yet have not taken it, and how it is that, whilst over-indulgence in Munich often leads to a beer-drinker's heart, it rarely does this in London, but often leads to cirrhosis of the liver. It may be that the bodies of the inhabitants of London differ from those of the dwellers in Munich, or the different results may be owing to the different composition of the alcoholic beverages in the two places, but it certainly does not help to say that in Munich alcohol has a selective influence on the heart and in London on the liver. But these are only two or three of the many difficulties that arrest us when we attempt to understand how alcohol causes disease, and which we try to gloss over by the phrase "selective action," as though alcohol were a living being capable of exercising choice. One of the greatest discoveries ever made in medicine will come to pass on the day when the mysteries now concealed by the phrase "selective action" are made plain, and we understand why, for example, the rash of measles comes first on the forehead, that of the scarlet fever on the chest, that of typhoid fever chiefly on the abdomen, and why, of all nerves in the body, the poison of diphtheria is specially harmful to those supplying the palate and the ciliary muscle.

Want of time prevents my bringing forward other instances of the years of delay in arriving at a truthful diagnosis that follow from cowardice in acknowledging that we do not know the cause of many symptoms, but it would not be difficult to do so, especially from among chronic diseases of the joints and diseases of the heart. I notice at the present time an increasing tendency to consider the muscle of the heart to be at fault. I believe that in the past we have not considered this nearly as much as we ought, and probably we have often overlooked disease of the cardiac muscle, but unless we check our clinical work by histology we run great danger of believing disease of the cardiac muscle to be present when it does not exist. I think I could show that the heart has often been said to be feeble or dilated on insufficient grounds and the orthodiagraph will, I think, teach us that we have frequently been in error when we have thought the heart altered in size, just as the clinical use of the manometer has taught us that the estimation of the arterial tension by the finger is not so accurate as we have been inclined to believe. But I have wandered from the point I am trying to press home—namely, that although we may make a diagnosis in the case of many diseases—for example, epilepsy—of which we do not at present certainly know the cause and which we recognise as a definite assemblage of symptoms—we should not make a diagnosis which implies a cause unless we have grounds from the previous experience of ourselves and others for prophesying what will be found at a post-mortem examination made with all the modern aids of histology, bacteriology, and chemistry if the patient died there and then. I quite admit that we shall often have to say we do not know and no doubt our diagnosis will sometimes be wrong, but at any rate our reticence and our mistakes will not retard, but will rather advance, the progress of medicine.

[Inability to confess ignorance is not, however, confined to the medical profession and Dr. Hale White quoted from the writings of Sir Alfred Wills and Mr. Baron Alderson passages showing that witnesses were much inclined to the same vice. He continued:]

Talking of unwillingness to confess our ignorance leads me to think of instances in which, while trying to treat medicine scientifically, we are woefully inaccurate, because we make excursions into sciences in which our training is inadequate. For example, the light and airy way in which some of us play with figures, as though there were no science of statistics, is astounding. Professor Karl Pearson truly says: "Approaching pathological inheritance from the modern statistical standpoint it is almost heartrending to notice the great amount of effort and energy wasted in the collection of data bearing on the inheritance of disease"; but, unfortunately, much effort hygiene the state of things existing on tramcars furnished with accumulators; these accumulators give off penetrating acid vapours which cause the passengers to cough and to sneeze. At certain times matters become absolutely insupportable not only inside the car but also on the platform. Short-circuiting is stated to be the principal cause of the acid vapours being given off. The general secretary of the prefecture of police replied that he had decided to do away with this particular system of traction but that in the meantime the administration will endeavour to take steps to amend matters.

The Liability of Medical Men.

The public are more and more taking up the objectionable position of suing the medical man in charge of a case when any untoward event happens. A case was heard on July 13th of this nature. A young girl, Mdlle. Peyronette, who was suffering from appendicitis, was successfully treated for this disease by Dr. Cormon. Part of the treatment consisted in the application of ice, with the result that the skin of the abdomen was "frost-bitten" and the patient is still suffering from the wounds not being completely healed. Her family sued Dr. Cormon on the grounds that the wounds had been brought about by his carelessness. Dr. Balthazard, the expert whose duty it was to draw up the report and who is an *agrégé* in medicine, summed up the charges made against Dr. Cormon by saying that if he considered it necessary to use ice he should not have used it for such long periods of time together but should have interrupted the application from time to time. Also, said the expert, Dr. Cormon had neglected to put a piece of flannel or linen between the ice and the abdomen. However, he felt himself compelled to add that this latter precaution was not always taken in the hospitals and that though Dr. Cormon had erred he had not been guilty of malpraxis (*faute condemnable*). On his side Dr. Cormon brought forward a number of eminent expert witnesses. Dr. Jalaguier stated in evidence that no limit could be put to the time for which the ice should be applied; it should be kept on until the local phenomena for which it had been employed had disappeared. Dr. Jalaguier, who is surgeon to the hospitals, added that he had often made applications of ice for a much longer period than Dr. Cormon did and was convinced that by them he had saved his patients' lives; some surgeons recommended the use of flannel and others said it was of no use; the appearance of sloughs did not contra-indicate the continued application of the ice, for the rule was, "of two evils choose the least." Dr. Dieulafoy declared that sloughing (*escarre*) could not be foreseen—it might happen in spite of all precautions; the application of ice was an approved method of treatment, and the formation of a slough was a frequently inevitable consequence. Dr. Cormon's treatment had been perfectly proper. Several other eminent surgeons testified to the same effect—viz., Dr. Kirmisson, Dr. Rénon, Dr. Triboulet, and Dr. Routier. Judgment will not be given for a week and the result will be announced in due course.

July 20th.

COPENHAGEN.

(FROM OUR OWN CORRESPONDENT.)

The Professorship of Pathology in the University of Oxford.

THE appointment of Dr. Georges Dreyer to the chair of general pathology in the University of Oxford deprives Denmark of one of its most prominent young men of science. In the comparatively short space of nine years, during which time he has been junior bacteriologist to the University of Copenhagen, he has been able to publish an important series of elaborate original investigations, chiefly on such subjects as agglutination, bacterial toxins, the action of rays of light, the sensitiveness of tissues to certain parts of the spectrum, the action and properties of radium, and the decomposition of enzymes. His devising of a very simple and sensitive method for the carrying out of the Widal test by means of dead cultures of the typhoid bacillus procured for him the post of director of the institute for the diagnosis of typhoid fever under the board of health of Copenhagen. He will be greatly missed both by his personal friends and by those at whose disposal he was always ready to place his extensive knowledge and wide reading. Professor Dreyer is well known in Oxford, having studied there in former years. In 1904 he was one of the speakers in the discussion on immunity that took place at the Oxford meeting of the British Medical Association.

Death of Professor Edmund Hansen Grut.

The Danish medical profession has sustained another heavy loss by the death of Professor Edmund Hansen Grut. The deceased, one of von Graefe's favourite pupils, was our first ophthalmologist in the modern sense of the word, and for many years he taught his specialty with exceptional success in the university at the outset as *privat-docent* and subsequently as professor of ophthalmology, after he had succeeded in overcoming the strong opposition in the faculty against the recognition of ophthalmology as a separate subject. Among the many scientific honours that fell to his lot, the one which perhaps he valued most was his being called in 1889 to deliver the Bowman lecture before the Ophthalmological Society of the United Kingdom.

Country Holidays for Town Children.

Among the many charitable institutions tending to improve the sanitary conditions of the poorer classes in Copenhagen none is, perhaps, more original and effective than the way in which an outing in the country is provided for a very large number of the pale and ill-fed children always to be found in a large town teeming with a manufacturing population. In many great cities charitable societies or wealthy individuals do a very considerable amount of good by sending parties of children out for a holiday in the country or at the seaside. Here also similar measures are taken, but naturally only a limited number can be cared for in this way and, what is, perhaps, most to be regretted, the children do not find a real home in their new residence. What makes it possible in Denmark during the summer months to confer the benefit of a home in the country on many thousands of poor Copenhagen children is the unique hospitality of just as many thousands of Danish farmers. For a number of years those good people have offered to take one child or more as their own into their families during the summer holiday without any recompense whatever. The offers are sent to the municipal school board of Copenhagen, and the teachers in the municipal free schools perform the delicate work of picking out those children whose state of health makes it most desirable for them to escape from the city during the heat of summer. The State authorities have recognised the importance of the movement by granting free passes over all the railway lines to any child who has got an invitation to a stay in the country. Some few days ago not less than 18,000 children were in this way sent out of town. Adding to these the poor children cared for by other means the total number may be estimated at 25,000, certainly a very considerable proportion of the indigent school children to be found in a city like Copenhagen, with a population of less than half a million.

The Destruction of Rats.

Our legislature has passed a new law directed against the rat nuisance. As the diseases the spreading of which is generally ascribed to rats, plague being a typical instance, never or hardly ever occur here it is only the destructive habits of the little rodents that have provoked the above-mentioned step. But in countries where the said diseases are more often observed it might perhaps prove useful to take similar measures. The State has decided to grant a sum of about £2000 a year for the distribution of rat-killing preparations and has, moreover, directed the municipalities throughout the country to pay about 1*d.* for every dead rat delivered to the proper officials. In order to prevent enterprising individuals from making money by wholesale breeding of rats heavy fines will have to be paid by those against whom it should be proved that they had either bred or imported rats for the purpose of selling them to the authorities.

Medical Incomes in Sweden.

A conspectus of the yearly income of Swedish public medical officers has been prepared by Dr. Andrew Alfvén. For 242 practitioners who had supplied the required information the average income derived from salary and practice was less than £400, varying from about £150 to about £900. The average cost of medical education was computed at £1000. The debt which their professional training has caused our colleagues to incur was on an average £750. The question at what age they had paid off, or thought they would be able to pay off, this debt was answered by 219 practitioners. Of these gentlemen 14 state that they see no way whatever out of the debt, 13 are doubtful, five name a very remote future, 20 had accidentally been freed from the debt, of the many sciences which bear upon his own; all that he can hope is that by the width of his own education he may be prevented from rushing in where angels fear to tread. Further, it is clear that many medical problems can be best solved by our working in conjunction with those versed in other sciences, from whom such of us as have the opportunity of studying medical problems should constantly seek help.

Yet another hindrance to the advance of medical knowledge is the acceptance of facts upon authority. In bygone days, in spite of Roger Bacon's teaching, this was commoner than it is now; indeed, through the dark centuries of medicine that preceded the discovery of the circulation of the blood everything was accepted on authoritative teaching, most of which was entirely wrong. Even in recent times there have been some remarkable examples. Thus the hæmoptysis of pulmonary tuberculosis was often ascribed to vicarious menstruation; although it occurs equally in men and women, it may be met with in females who are of such an age that menstruation does not take place and it has no monthly periodicity. But perhaps the most striking instance of subservience to authority was the almost universal habit of bleeding solely because the teaching of the day said that people should be bled. Often patients were actually bled to death, yet those who did it were so blinded that they ascribed the death to the illness and not to the bleeding. If he had done nothing else Marshall Hall would have proved his genius by pointing this out, as he did in his "Researches Principally Relative to the Morbid and Curative Effects of Loss of Blood." To take one case among many that he gives: a man fell from a scaffold and fractured his ribs; he was taken to the hospital and bled to 18 ounces. 24 hours later 18 ounces more were taken from him and about seven hours afterwards 18 ounces more, and 15 hours later a further 20 ounces. "The pulse after this time became a mere flutter and the man survived only a few hours." Could anything illustrate subservience to authority more strongly?

Not so very long ago that extremely powerful poison, antimony, was given for many diseases because it was stated by authorities to do good. No one would now contend that any considerable proportion of the thousands of patients who took antimony were one whit the better for it. When a student begins his work he must for a little while accept some statements upon the authority of his teacher; but with every day of his career the necessity for this becomes less and less, for medicine is a science in which nature performs experiments on every patient that those who have eyes to see can watch and so observe for themselves if the statements commonly made are correct. I would say to all but the youngest students: accept nothing on authority but look for yourselves and see if the usual teaching is true; believe nothing you do not see, be sceptical about everything you are told. Do not think I mean that no respect should be paid to the experience of skilled clinical or pathological observers or experimental pathologists, but all of us should be always on the alert to see if they are correct, and we should respect those who are.

Speaking of the use of antimony and venesection as illustrating the harmful effect of authority reminds us that no department of medicine shows this better than that which deals with treatment. Sometimes authority in one country advises different treatment from that employed in another. Thus, whilst in England we often give strychnine when the pulse is feeble, in Germany camphor is used for the same condition. This seems absurd; one or the other must be the better. Often little attention is paid to the natural course of the disease towards recovery; for example, many methods of treatment by drugs, electricity, serums, or operation are said to benefit exophthalmic goitre, regardless of the fact that if the patient is put to bed and kept quiet she will usually recover without any other treatment. With many diseases the natural tendency to get well is so great that unless there is a strong consensus of opinion as to the efficacy of one particular mode of treatment—for example, iron for chlorosis, mercury for syphilis, and thyroid gland for myxœdema—probably no special treatment by drugs does any good. It may be laid down that when more than two drugs are praised as benefiting any disease probably no one that we know does so.

Unreflecting adhesion to authority has a particularly serious effect in keeping back the advent of correct knowledge, for in the first place, when the authority is found to be wrong, much energy that might be utilised in the search for truth is expended in demolishing that which is false, and in the second place it seems almost a law that we should rush to extremes of thought, so that having been for years wrong in one direction we travel for years wrongly in another course before attaining the true position. For example, for many years after it was shown that bleeding had been frequently practised for diseases in which it did harm it was very rarely done and many patients were therefore deprived of the relief it would have given them, and it is only now that we have learnt to know correctly when to employ it. The history of our views upon the relationship of the different varieties of Bright's disease shows the same thing. At one period it was taught that many of the acute cases passed into interstitial nephritis, then it was believed that none did. "It is almost always the unhappiness of a victorious disputant to destroy his own authority by claiming too many consequences or diffusing his proposition to an indefensible extent." Much of the excessive zeal for treatment by drugs arises not only from an unwise adhesion to so-called authority, but from a lack of appreciation that pathology is the basis of all medicine. The primary duty of a physician is to find out what is the matter with his patient; proper treatment can only be secondary to that. All treatment apart from a correct diagnosis, which in most cases should include a correct visual impression of the way in which the body is disordered, is bad, and may well lead to more harm than good. Another reason for incorrect treatment is that many say, "You must do something." I can never see the reasonableness of this. The very fact that the medical man does not know what to do is actually used as a reason why he should do something; surely it is the very reason why he should do nothing, for he may well do more harm than good. To know when to interfere and when not to interfere with nature is a fine test of the sagacity of a clinical physician Think of the harm that was done not many years ago by the wholesale administration of antipyretic drugs. Do not, however, imagine I am urging that treatment is rarely of use. Far from it. Never at any period in the history of medicine has treatment been more skilful than now, and never did our art save more lives than now. We have only to look back a little to see that we have improved. A hundred and fifty years is a short time in history, yet we find such a distinguished physician as William Saunders in the year 1767 recommending that a sufferer from the "iliac passion" should have crude mercury given him by the mouth, tobacco fumes by the anus, and that cold water should be thrown on his body. I am only pleading that we should try to observe and think clearly and accurately each for himself; if we do this the gibe that medical men treat diseases of which they know little by drugs of which they know less will pass away.

The last point to which I have time to draw your attention is that it usually requires considerable trouble to train ourselves to receive new ideas properly and by failing in this respect we retard the progress of medical thought In this matter there are two chief kinds of mind. Those having the one usually claim that they are critical, but they are obstructive rather than fair critics. For the most part they are extremely slow to assimilate anything new, strange to say, they frequently pride themselves on this and take great comfort from the sad fact that many suggestions which when first promulgated appeared fruitful have turned out to be barren. Such as these are satirised in Mr. Thomas Diafoirus whose father said of him with pride "that he is blindly attached to the opinions of the ancients and that he would never understand nor listen to the reasons and experiences of the pretended discoveries of our century concerning the circulation of the blood and other opinions of the same stamp." Those having the other are easily enticed away by new notions just because they are new; they absorb new ideas too rapidly without digesting them; in popular language they are ready to swallow anything. Fortunately our profession contains many who fall into neither of these classes, because they have an evenly balanced mind trained to estimate the value of novel suggestions.

Pardon me for having in these fragmentary remarks only stated what you all know and what many have taught at various times during many centuries. My excuse for urging a plea for accurate thinking is that the more accurately we think the more rapidly will medicine progress. Perhaps, having listened to me so far, you may despair of advance; but a moment's glance at medicine of, say, a few years ago will show that we have gone forward notwithstanding our many mistakes For, happily, "Time effaces the fictions of opinion and confirms the determinations of nature."

original condition of the nervous centres the latter once more become capable of working normally. Patients suffering from disorders of the alimentary or circulatory system due to other causes than the above-mentioned ones have specially to be careful.

The Ultra-microscope in Hæmatology.

Dr. Neumann has communicated to the *Wiener Klinische Wochenschrift* the result of a series of interesting experiments which may prove to be useful in the diagnosis of diseases of the alimentary canal. Using the ultra-microscope, which has a magnifying power of 40,000 diameters, he examined both his own blood and that of other individuals, some of them being in good health and some of them suffering from various ailments. Among the red and white corpuscles he found a varying number of extremely small round granules which were constantly in molecular movement and have been called hæmokonia. During these investigations it was discovered that when fat, such as butter or lard, was added to the food these granules increased very greatly in number so that the whole of the visible field was covered by them. The increase began three-quarters of an hour after the ingestion of fat and reached its maximum about three-quarters to one hour later. For studying these phenomena it was best to use ordinary microscope slides about two millimetres thick. The best time for these experiments was the morning, when the stomach was empty. The patient was given a breakfast consisting of tea, white bread, and about one-third of an ounce of butter, or 13 ounces of milk without anything else. This was to be preferred because nearly all patients can take it. After three-quarters of an hour the first examination of the blood was made and subsequent examinations were made every half hour for four hours after the ingestion of the test meal. The patients on whom Dr. Neumann made his observations were 100 adults and 18 infants. He distinguishes five stages of the appearance of the minute granules. In the first stage there were no granules to be seen; the second he called "few"; the third he called "many," when the granules were to be seen in heaps between every few blood cells; then came "abundant"; and, finally, "enormous numbers." It was difficult to explain every stage but an observer soon became accustomed to the expressions. A remarkable and important difference was found in the preparations obtained from healthy and diseased persons. In all patients suffering from disorders of the stomach or other parts of the alimentary canal the "ultra corpuscles" were either absent or else they appeared at a much later stage than usual—namely, in from five to eight hours and in small quantity.

Vital Statistics.

The report of the Registrar-General for the second quarter of 1907 shows that the abnormal conditions prevailing since the last half year still influenced the general health of the population. The violent changes indicated by the varying barometric and thermometric readings could be followed in the figures for diseases of the upper respiratory tract, and the theory of the intimate connexion between low barometric readings and cerebral hæmorrhage receives some countenance from the figures of the report. No case of small-pox was notified during the quarter in question, whilst infectious diseases, such as measles, scarlet fever, and whooping-cough, were abundant both in the industrial centres and in the rural districts. The average mortality in Vienna for the last half year was 18·2 per 1000, showing a slight improvement as compared with the figures for the first quarter of the year due to the better returns of the second quarter. Epidemic cerebro-spinal meningitis has been notified in 45 cases. It must be added, however, that sporadic cases of this disease are found throughout the whole year in the city. The mortality was low, especially after using the pyocyanase of Dr. Jehle. Diphtheria was decidedly prevalent, every week bringing about 35 or 40 fresh cases; the mortality from this disease was below 5 per cent. in private practice and below 3·5 per cent. in hospital practice. As a rule the virulence of the Löffler bacteria was noted to be rather less than in former years. The weather was unfavourable for patients suffering from pulmonary tuberculosis and the deaths from this cause rose to 120 per week. Typhoid fever has lately assumed a more severe type. Perforation of the intestines seems to appear oftener, whilst hæmorrhage in the mucosa is also very often associated with it, so that Professor Schlesinger in a communication to the Vienna Gesellschaft der Aerzte did not scruple to speak of the "Vienna type" of typhoid fever. The births were about 1000 per week, with 86 stillbirths, and the mortality of infants under 12 months was 107 per 1000 births.

July 22nd.

Obituary.

JAMES DUNSMURE, M.D. EDIN., F.R.C.S. EDIN., LL.D.

THE intimation of the death of Dr. Dunsmure was a surprise and a shock to the profession in Edinburgh. He died on July 15th, from sudden heart failure, when to all appearance he seemed to have been progressing satisfactorily after a surgical operation. Dr. Dunsmure was the son of a well-known Edinburgh surgeon who was one of a number of interesting men who flourished in the middle Victorian time. The son, who is the subject of this notice, took the degree of M.B. at Edinburgh in 1867. After completing his education on the Continent he was associated with his father in practice. In 1870 he took the degree of M.D. and a year later was elected a Fellow of the Royal College of Surgeons of Edinburgh. He held a number of appointments as physician or surgeon to various institutions; but the most important post which he held was that of physician to the Royal Hospital for Sick Children. He was an ex-President of his College and it was during his occupancy of the Presidential chair that the University of Glasgow conferred upon him the honorary degree of LL.D. At the time of his death he was a member of the Council of his College and also an examiner for that College on the Triple Qualification Board. He was a member of the various Edinburgh medical societies. His personal qualities were very attractive and endeared him to a large circle of medical and lay friends. He was kindly, genial, and hospitable, with a high sense of honour and good business faculty. He was a keen sportsman: he fished, shot, and played golf and was no mean hand at any of them. He was fond of literature and an elder in St. Andrew's Church. He was, indeed, a man of cultured tastes who enjoyed life and made life pleasant to those around him. His wife died many years ago, about a year after their marriage, and the child of that marriage, a daughter, mourns the loss of a devoted parent. The funeral service was held in St. Andrew's Church and was attended by many of the leading members of the profession in Edinburgh. He was buried in the Dean Cemetery on July 19th.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Willem Koster, formerly professor of anatomy in the University of Utrecht.—Dr. Ferdinand Levison of Copenhagen, at the age of 63 years. He was the author of many important papers dealing chiefly with gouty and rheumatic conditions.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the quarterly examination in Practical Pharmacy just completed the following gentlemen were successful:—

Stanley Denovan Adam, St. Mary's Hospital; Charles Vernon Anderson and Sydney Vere Appleyard, St. Thomas's Hospital; Noel William Berry, St. George's Hospital; Herbert Stuart Blackmore, University College Hospital; Tobias Rustat Hemsted Blake, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Owen Henry Bowen, St. Bartholomew's Hospital; Thomas Stratford Bradburn, Birmingham University; Gordon Normanby Brandon, St. Thomas's Hospital; Thomas Creswell Brentnall, Manchester University; Roger Orme Bridgman, St. Bartholomew's Hospital; Herbert Hayward Budd and John Head Burdett, St. Mary's Hospital, Howard James Barrell Cane, B.A. Cantab., Cambridge University and Guy's Hospital; William Edgar Carter, Leeds University; Henry James Clutterbuck, Middlesex Hospital; Francis Garland Collins, London Hospital; Robert Crawford, B.A. Cantab., and Alfred Edgar Cullen, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Christopher Robson Dudgeon, Westminster Hospital; Percy Albert Stanley Dyson, Guy's Hospital; George James Frank Elphick, St. Mary's Hospital; Cecil Ledward Forde, B.A. Cantab., Cambridge and Liverpool Universities; Ashbury Joseph Stuart and suppurate. Indeed, the conditions which generally prevail are so unfavourable to accidental implantation in human beings that the event might be regarded as well-nigh impossible and scarcely worth the trouble of investigation, were it not for the occasional occurrence of what appear to be examples of successful implantation in different parts of the body of the same individual. Such cases have long been known under the name of *auto inoculation*, and it is to them that I shall devote this address. For the key to the problem of the communicability of cancer in human beings must surely lie in the study of auto-inoculation. If auto-inoculation can be proved on such evidence as would be admitted in a court of law, there is a *primâ facie* case for contagion. And, if the proof of auto-inoculation falls through from lack of sufficient evidence, whether in quality or quantity, it is no longer worth while to pursue the study of contagion from individual to individual. Seeing the many papers and theses which have been written and the number of cases which have been brought forward to prove auto-inoculation, the case in favour of it, if there be a case, ought to have been proved conclusively long years ago.

B t f r the same reason as for the case of contagion—the r flimsy character of the evidence, the possi- ning many of the cases on some other theory, of auto-inoculation under conditions in expected to take place—there is as yet no question. The only cases which should be se which fulfil the following conditions: ust be of the same variety in the primary l in the reputed contact-cancer. The identity se must be proved by microscopical examination. ary disease must have been exposed at the time at n contact is known to have taken place, and there should such evidence of contact of the primary carcinoma with the seat of the reputed contact-cancer as would satisfy a jury.

The necessity of proof by microscopical examination is exhibited in the following case. I was informed that a certain museum in London contained a specimen which would interest me. It was a case of primary epithelioma of the gum, with a small, isolated epithelioma of the cheek exactly opposite to it. My informant offered to bring the microscope slides to my house for examination, but the promise was so long of fulfilment that I drove one day to the museum in which the specimen lay. The curator of the museum met me with an expression of disappointment and told me he was ashamed to confess that, although this specimen had been exhibited to various persons as an example of the contagion of cancer, it had never been examined microscopically until my friend had informed him that I wished to see the sections, when he had at once proceeded to cut them, with the result that while the primary disease was typical epithelioma the ulcer of the cheek only exhibited the ordinary characters of inflammatory ulceration. Yet both he and the surgeon who had operated had been previously convinced that the disease was of the same nature in both the sores.

Although a large number of cases of reputed auto-inoculation may be found in surgical literature, it is remarkable how few of them fulfil the conditions which I have laid down as essential to their acceptance. There are two of them which merit the gravest attention, for they are cases in which a portion of a tumour was deliberately implanted in another part of the body of the patient who had grown the tumour. Professor Cornil brought one of them before the French Academy of Medicine in 1891, but the tumour was a fibro-sarcoma, and as my inquiry is limited to carcinoma I cannot use it. The other case was thought by Professor Hahn, who related it at the Berlin Medical Society in 1887, to be an absolute proof of the possibility of auto-inoculation and would undoubtedly have come down to us as such had not Professor Virchow happened to occupy the chair that day. Hahn cut out three nodules of a disseminated carcinoma and planted them apart and in quite distant parts of the body of the patient. All three nodules took root and grew, and were examined microscopically and were found to present the characters of the primary disease. Professor Virchow asked if the skin in which the nodules were growing had been transplanted with them, and receiving an answer in the affirmative objected to the conclusive nature of the experiment on the ground that the surgeon had transplanted the soil in which the nodules grew and without which they might have failed to grow. And the objection of that most sagacious of pathologists and philosophe must be admitted, so the case falls through. I am not awa that any direct experiments, which are so strongly co demned by our profession throughout the world, have sin been practised.

In order to supplement the very barren material supplie by surgical literature with new and original material, published a short letter in our journal last November askin for cases of reputed contagion of cancer, whether in th same individual or from one individual to another. In repl I received some very kind letters, some of which containe cases which were incomplete in one respect or another, wit one exception to which I shall presently refer. On the othe hand, there was one letter which contained no actual case i point but which interested me very much. It was from D J. H. Dauber, physician to the Hospital for Women in Soho and was to this effect: "Replying to your letter in the *Britis Medical Journal* of this week, I need hardly remind you ho very common it is for a squamous-celled carcinoma on on labium of the female to affect the opposite one, whether i be the labium minus or majus. It infects the opposite sid of the vulva by direct contiguity as surely as a condyloma. Time only is necessary and a certain amount of moisture to make it invariably the rule in my opinion ......" Now I had no idea that this was so, for cancer of the vulva has comparatively rarely come under my notice, either in hospital or private practice. I lost no time in asking two or three of my obstetric friends their experience, and I consulted two or three books in which I thought some reference might be made to it. Neither my friends nor the books confirmed Dr. Dauber's statement, and I was disposed to believe either that he had exaggerated the frequency of the occurrence or that his experience had been very exceptional. I even wrote to suggest this to him. And I might have set the matter on one side as little worthy of credence had it not happened that my assistant in this investigation wrote shortly afterwards to tell me that he had looked out all the cases of cancer of the vulva which had been in the wards of St. Bartholomew's Hospital in the past ten years, that they were 23 in number, and that in five of the 23 cases the disease was on the two sides. His words were: "In five out of the 23 cases of epithelioma of the vulva I find that one labium was first affected and subsequently the other labium. This is not including those cases in which the disease seems to have spread by direct extension ...." Thus Dr. Dauber's statement, though not confirmed to the full, was powerfully supported; and I began to suspect that this was one of those curious instances in which facts lie at our very feet and are either overlooked or only casually noticed until our attention is forcibly directed to them and to their import. I instantly issued a circular letter to a large number of specialists or persons interested in gynæcology, begging of them cases of contact-cancer of the vulva; and as about the same time I discovered an excellent case of reputed contact-cancer of the larynx by Dr. D. Newman of Glasgow in the Transactions of the Clinical Society I issued a similar letter to those persons who are interested in laryngology. I received, through the kindness of my friends, quite a large number of replies. Those of the gynæcologists exhibited a singular divergence of experience; for, while some of the writers had not, so far as they could recollect, seen a single case in point, several of them had seen at least one case, and two or three of them had seen a number of such cases. I do not attempt to explain this divergence of experience, but of course the positive experience is much more valuable than the experience which is negative. Unfortunately, very few of the cases which were reported to me were complete in all respects.

[Mr. Butlin here proceeded to give details of 15 cases of auto-inoculation of cancer, undoubted or apparent. Exigencies of space forbid our quoting all the cases and we have therefore made a selection. So far as possible we have not limited the selection to those which were apparently undoubted cases of auto-inoculation, but, as will be seen, we have given one apparently certain case and one doubtful case, in those sections, that is to say, where there were more than one case. We have kept Mr. Butlin's original numbering, therefore the numbers are not consecutive. Of carcinoma of the vulva Mr. Butlin gave five cases; of the larynx, three; of the lips, one; of the jaws, one; of the uterus and vagina, one; of widely separated parts of the body, two; and of cases of auto-inoculation on unbroken surfaces, two.]

informed by Mr. Badcock that private vaccinations at a surgery did not necessitate either correspondence or visits. Although a few members of the board who are opposed to vaccination were opposed to increasing the minimum (which they consider ought not to exceed 1*s.*) the deputation made a favourable impression on the board. It was admitted that members had previously had no idea that a public vaccinator had to do so much for his fee. One of the ladies remarked that she believed in everybody being fairly paid and therefore she proposed a return to the 5*s.* minimum. A gentleman suggested 3*s.* 6*d.*; this would probably have been agreed to had not another member discovered that proposals were out of order since the medical men had not refused to accept the fee of 2*s.* 6*d.* The question was therefore adjourned.

Royal College of Physicians of Edinburgh.—A quarterly meeting of this College was held on July 16th, Dr. C. E. Underhill, the President, being in the chair. The President made feeling reference to the loss which the College had sustained by the death of Sir William Tennant Gairdner. On a ballot the following candidates were admitted to the Membership of the College: James Ritchie, M.D. Edin., Edinburgh; David Halliday Croom, M.D. Edin., Edinburgh; and Leonard Horner Bryson, M.B, C.M. Edin, St. Andrews. The registrar reported that since the last quarterly meeting of the College 18 persons had obtained the licence of the College by examination. Dr. G. Lovell Gulland, F.R.C P. Edin., was recognised as a lecturer on medicine. The regulations regarding the single licence and Membership and Fellowship of the College for the ensuing year were approved.—By vote of the College James William Ayres, a Licentiate of the College, was expelled from the College and deprived of his licence to practise, as granted by the College, and of all his rights and privileges as Licentiate.

The London Hospital Medical College (University of London).—On July 17th Mr. Hudson E. Kearley (Parliamentary Secretary to the Board of Trade) distributed the prizes and certificates to the successful candidates in the library of the Medical College. Mr. Douro Hoare (chairman of the College board) presided, and the Hon. Sydney Holland (chairman of the hospital), the members of the house committee and staff, and a large gathering of visitors were present. Unfortunately Mr. Munro Scott (the warden of the College) was unable to be present as he was only just recovering from an operation; needless to say he was greatly missed by all. Mr. Douro Hoare, in asking Mr. Kearley to distribute the prizes, alluded to the prosperity of the College and thanked Mr. Kearley for his munificent gift to the pathological institute which had enabled the College to develop the branch of its work which promised good results in the future. Mr. Kearley, in addressing the meeting, stated that he had been much impressed by the efficiency of the organisation of the hospital and the good spirit in which it was carried on; while the Hon. Sydney Holland, in his speech, complimented the nursing staff on its efficiency and the hospital upon its nearness to completion The following prizes were then distributed:—Price scholarship in science: £120, Mr. H. B. Walker. Price scholarship in anatomy and physiology: £60, Mr. E. J. Fearnsides. Entrance science scholarships: £60, Mr. F. Sanders; £35, Mr. R. A. Rowlands. Buxton scholarship in arts: £30, Mr. J. W. Clouston; £20, Mr. L. M. Ladell. Epsom scholarship for students of Epsom College: Mr. R. K. Mallam. Medical scholarship: £20, Mr. R. B. Lloyd; honorary certificate: Mr. A. R. Jordan. Surgical scholarship: £20, Mr. P. H. Bahr; honorary certificate: Mr. A. R. Jordan. Obstetric scholarship: £20, Mr. G. Ley; honorary certificates: Mr. G. H Davy and Mr. D. Loughlin. Duckworth Nelson prize: £10, Mr. R. B. Lloyd; honorary certificate: Mr. A. R Jordan. Senior Letheby prizes: £10 each, Mr. R A. Rowlands and Mr. J. A. Tsoi-A-Sue (equal) and Mr. F. Sanders; honorary certificates: Mr. W. S. Wildman, Mr. C. C. Beatty, Mr G. F. Bradley, and Mr. H. B. Walker. Junior Letheby prize: £10, Mr. J. R. O. Stephens: honorary certificate: Mr. E. H. Heaton. Anatomy and physiology scholarship: £25, Mr. E. B. Morley; honorary certificates: Mr. G. Taylor, Mr. R. H. Candy, and Mr. H. Neame. Anatomy and biology scholarship: £20, Mr. H. B. Walker; honorary certificate: Mr. R. A. Rowlands. Minor surgery prizes: £12 10*s.* each, Mr. T. C. Reeves and Mr. E. C. Lindsay; £10 each, Mr E. H. Rainey and Mr. Stanley Boyd; £5, Mr. H Neame. Practical anatomy prizes: £6, Mr. E. H. Rainey; £4, Mr. J. G. Mosely and Mr. B. Bernstein (equal). Anderson prizes:

The Victoria University of Mancheste
Dr. Graham Steell, who has been appointed by the Cou
professor of medicine in the University, has had a long an
intimate connexion with the Royal Infirmary of Manchester, having acted successively as resident medical officer and physician in that institution, of which he is at present the senior physician. For many years he has been a lecturer, first in the Owens College and subsequently in the University where he has held the posts of lecturer on clinical medicine and also of lecturer on diseases of the heart.—At a meeting of the friends of the late Professor J. Dreschfeld held recently it was agreed to make arrangements for securing some permanent memorial of him in Manchester.—The following appointments have been made: Junior Demonstrator in Anatomy, Mr. A. E. Quine, M.B., Ch.B. Vict.; Demonstrators in Anatomy for the Winter Session, Mr. S. H. J. Kilroe, M.B. Lond., and Mr. T. W. Todd; and Junior Demonstrator in Physiology, Mr. Philip Ferguson, M.B, Ch.B. Vict.—The dental department forms an integral part of the faculty of medicine. Instruction adapted to the requirements of students preparing for the B.D.S. degree and the dental diplomas of the University, the Royal College of Surgeons of England, and other licensing bodies is given during the winter and summer sessions both at the University and at the Victoria Dental Hospital, and the latter is well provided with the appliances necessary for carrying on the work in a thoroughly efficient manner. Two dental surgeons are in attendance when the hospital is open, and are always ready to advise and to direct the students and the demonstrators and house surgeons are constantly present to overlook the work and to render every necessary assistance. Communications concerning classes, fees, conditions of entry, attendance of students, &c., should be addressed to the Dean of the Medical Faculty, the University, Manchester. The Dean of the Dental Hospital may be addressed at the hospital, Devonshire-street, All Saints, where he may be seen on Friday mornings from 9 to 11.30, or at other times by appointment.

The Maitland Cottage Sanatorium: an Interesting Scheme.—A meeting was held at Kingwood, Peppard's Common, on July 20th which had for its object the promotion of a scheme for the development of the adjoining Maitland Cottage Sanatorium, but the subjects discussed were of more than local interest. The Maitland Cottage Sanatorium has been in existence for some six years under the direction of Dr. Esther L. Carling for the benefit of the poor suffering from tuberculosis in its early stages. Fortified by the experience so gained it is proposed to enlarge the sanatorium, but it is also proposed to append a labour colony and a kindergarten school to the institution. The meeting was presided over by the Hon. F. W. D. Smith, M.P., and speeches in support of the scheme were made by Professor W. Osler, Dr. S. Davies (medical officer of health of Woolwich), and others. Professor Osler expressed a very strong opinion that tuberculosis should be added to the list of notifiable diseases. After quoting the Registrar-General's statistics of mortality from tuberculosis he divided those suffering from the disease roughly into two classes: (1) the advanced cases for which special isolation should be provided; and (2) cases in the early stages of the disease which must be dealt with in sanatoriums similar to the Maitland Cottage Sanatorium. He further dwelt on the educative value of such establishments as spreading among the poor a much needed knowledge of hygiene. Dr. Davies then spoke to the practical has probably a considerable power of resistance. And it does not in the least affect the argument that cancer may extend to it by direct continuity, for there is scarcely a tissue of the body which is not liable to the continuous extension of cancer. The discharges from the ulcer do not lie on the upper lip as they would do on the lower lip if the primary disease were situated on the upper lip. The upper lip is not frequently excoriated or cracked as is the lower lip in many persons; and the lips are so frequently wiped or even washed in the course of every day that the cancer cells have very little chance of remaining sufficiently long upon it to effect a permanent hold.

Upper and Lower Jaw.

CASE 10.—(I am indebted for this case to Mr. C. Stonham, and for the notes to Mr. J. M. G. Swainson, the surgical registrar to the Westminster Hospital.) A man, 60 years of age, was admitted into Westminster Hospital with a large cancerous ulcer of the alveolar portion of the back part of the right side of the lower jaw, which extended down the side into the floor of the mouth. Immediately opposite to the growth there was, on the alveolar process of the upper jaw, an ulcer of the size of a sixpence. The history was very defective, but it appeared that the patient had pulled out a loose tooth from the lower jaw about three months previously and had noticed that a piece of the gum came away with it. A fortnight later the same occurrence had been noticed in regard to another tooth; but he was not even aware that there was anything the matter with his upper jaw. Mr. Stonham removed the disease of both jaws and the adjoining parts, together with a number of affected glands, and I went down to the Westminster museum to see them. They were most kindly examined for me by Mr. Swainson who reported that the disease of both jaws was carcinomatous. The only doubt in this case was whether the upper and lower alveoli came in contact at the back, but Mr. Stonham was convinced that this was so.

Uterus and Vagina.

CASE 11.—In the *Annales de Gynécologie et d'Obstétrique*[3] Hartmann and Lecène describe the case of a woman, aged 49 years, who had an ulcerated tumour of the neck of the uterus. She had had pain for eight years and discharges of blood for four years. On the right posterior lateral wall of the vagina, three centimetres from the neck of the uterus, was an uneven ulcerated surface, with hard edges, but moving freely on the subjacent tissues. The diseased uterus and the ulcer of the vagina were removed by Hartmann. Microscopical examination showed that the disease in both places was of the same variety—cylindrical carcinoma. The carcinoma of the vagina stood in the midst of squamous epithelium and was quite circumscribed. The surrounding tissues were examined and were found to be free from carcinoma and the lymphatic vessels did not contain carcinoma cells.

This case is the more convincing because the vagina is lined with squamous epithelium and is, therefore, subject to squamous, not to cylindrical, carcinoma.

Distant Parts of the Body.

CASE 12.—Sir William Macewen of Glasgow was so good as to supply me with the following interesting case. A patient with an ulcerated epithelioma of the lower lip consulted him, and during the consultation pressed his forefinger against the ulcer and then quickly rubbed the tip of his nose with the same finger. The nurses at the home to which he was sent for operation independently noticed this curious habit, and when the gentleman was asked why he did it he replied that gentle pressure on the ulcer relieved a tingling sensation in it, but that he was not even conscious of his trick of rubbing his nose after he had pressed his finger on the ulcer. The growth of the lip was removed and was found to be an epithelioma. 20 months later he returned to Sir William Macewen with a large ulcerated patch on the tip of his nose which extended from one ala to another. He had first noticed it about three months after the operation on the lip. It was removed and presented the same histological characters as the cancer of the lip.

I have thus brought together a certain number of cases which fulfil the conditions which were laid down in the early part of this address. They are not so numerous but I would fain have more of them, and I hope to do so by the kindness of some of those who are present here to-day and of those who may chance to read the address. But I think they are too many and too constant in the circumstances of their occurrence to be explained on the theory of coincidence. If two persons meet on a certain day at a certain place the meeting may be regarded by those who witness it as a chance, curious or not, according to the conditions which are associated with it. But if the meeting is frequently repeated under similar conditions the witnesses begin to suspect that there is something more than mere chance, especially if one of the persons is male, the other female, and a cause is sought for. So the repetition of such occurrences as I have described appears to be too frequent to permit them to be regarded as coincidences. But there is much more in the evidence than the mere repetition. It will be observed that I have brought forward only two cases in which the reputed contact-cancer was on the skin and that all the other cases were on surfaces which are covered with mucous membrane, that they were most frequent on mucous surfaces which are usually moist, that they were most frequent on mucous surfaces which are generally not kept scrupulously clean, that they occurred most often on surfaces which were constantly or frequently in contact, such as the opposite sides of the vulva, and less often on surfaces which only come in contact from time to time, with the exception of the upper and lower lips. All these are circumstances which tend to confirm the theory of contact-cancer. They are such as might be expected from *a priori* reasoning. And there is yet one more important point. The reputed contact-cancer in one of them was of a variety which does not naturally grow as a primary disease in the part where it occurred.

I do not know whether I shall be deemed to have proved the case of auto-inoculation. For myself, I think the evidence is conclusive. But then I must confess that my belief that carcinoma is a parasitic disease and that the carcinoma cell is the parasite strongly disposes me to believe that the disease should be capable of auto-inoculation.

Is a broken surface essential to successful auto-inoculation? Had I been asked that question a few months ago I should have probably replied, I think it is. But the following case, for which I am indebted to Dr. E. Michels, suggests that auto-inoculation may occur on a plain, unbroken surface. So that I should now be disposed to say that it probably almost always precedes and is helpful rather than essential to auto-inoculation.

CASE 14.—A woman, aged 40 years, was admitted into the German Hospital with a large tumour in the situation of the left kidney and a history of hæmaturia of about four years' duration. Cystoscopic examination discovered a papillary growth at the orifice of the left ureter. This was removed through a suprapubic incision and it was hoped that the swelling of the kidney would subside, but as it did not do so and the hæmaturia continued the kidney was removed a few weeks later. It was found to contain a large papillary tumour like that which had been removed from the ureter. The microscope showed that the disease was malignant and of the same variety in both tumours. At the time of the first operation a considerable portion of the ureter above the growth was removed and found to be perfectly healthy. By the kindness of Dr. Michels I am able to exhibit drawings of the microscopical structure of both tumours. The last account of this patient was that she was suffering from a large mass in the abdomen, presumably due to disease of the lymphatic glands.

A corresponding case is described by Hartmann and Lecène.[4]

These cases and those in which the material is conveyed into the end bronchi of the lung, and there takes root and grows, of which a good example is recorded in the *Transactions of the Pathological Society* by Moxon, may be placed in a special class, as it were, between metastasis and auto-inoculation. The cancerous material does not lie surrounded by what we term nutrient fluids, such as the lymph and blood, nor is it constantly or frequently in contact with, or rubbed into, the part in which it succeeds in gaining a foothold.

I cannot deal with other side issues which naturally present themselves in connexion with the question of auto inoculation, for time will not permit it. Such, for instance, as the length of time which may elapse before the appearance of the reputed contact-cancer. But I must not pass whether his attention had been called to the case of a boy who died in Croydon on April 29th last as the result of vaccination; whether he was aware that the case was investigated by Dr. S. M. Copeman of the Local Government Board; that the child had sores on the head, face, and arms, and lingered in agony for three months; whether he would say if he was still supplying public vaccinators with the same class of lymph; and whether he would lay Dr. Copeman's report upon the table.—Mr. John Burns answered: I am aware of the case referred to, although I did not know that the child lingered in agony for three months, nor had I been informed of his death. The case was investigated by Dr. Copeman and several medical men. 20 other cases were vaccinated with the same lymph as this child and, so far as was ascertained, the case in question was the only one in which the child subsequently had sores. These sores appear to have been, in fact, "the bromide rash" and to have been due not to vaccination but to doses of bromide of potassium administered by the mother on account of the fits from which the child suffered. It is estimated that 175 grains of the drug were given to him. Dr. Copeman's report is a confidential document and I could not undertake to lay it on the table of the House.

[4] Loc. cit.

Medical Officers and the Factory Act.

Mr. Ramsay Macdonald asked the Secretary of State for the Home Department whether his attention had been drawn to Table 8 in the report of the Chief Inspector of Factories for 1905, wherein it was shown that the number of names of outworkers received was greatly in excess of the number of visits made by the medical officers of health in Sheffield, Belfast, Worcester, Ipswich, Gloucestershire, West Ham, Westminster, and other areas; and what steps he proposed to take to make this inspection efficient.—Mr. Gladstone said in answer: Yes, sir, this table was included in the chief inspector's report by my directions with a view to the improvement of the present conditions. The steps that have been taken by me to improve the administration of the home work provisions of the Factory Act by the local authorities have been to issue a circular on the subject to the authorities and the medical officers of health, calling their attention to the importance of a thorough administration of the Act and, secondly, to propose that the matter shall be discussed at a conference with medical officers of health which it is intended to hold at the Home Office in the autumn.

Mr. Ramsay Macdonald then asked the right honourable gentleman whether his attention had been drawn to the fact, as shown in the annual report of the Chief Inspector of Factories for 1906, that 634 medical officers of health still neglected to perform the statutory duties imposed on them by the Factory and Workshop Act to report to the Home Office regarding their administration of that Act; and how long the Home Office proposed to allow this neglect to continue.—Mr. Gladstone replied: The great majority of the medical officers who have failed to send in reports—namely, 477 out of 634—are in Ireland. Under the Irish Public Health law the medical officers other than the few superintending medical officers are not required to make any report to the local authority and I am advised that it is doubtful how far in consequence any obligation is placed upon them by Section 132 of the Factory Act. As I have already stated, a special circular was sent out last year by the Home Office calling the attention of the local authorities and medical officers to their duties in regard to home work, and I propose to communicate specially this autumn with those local authorities from which no reports were received in 1906. I may add that in many districts from which no report is sent the Factory Act has little or no application, and the omission is comparatively unimportant.

Mr. Ramsay Macdonald put a further question to the Home Secretary as to whether his attention had been drawn to the figures in the annual report of the Chief Inspector of Factories, showing that in 1905 in the borough of Stepney the medical officer reported only 32 inspections of outworkers out of 8993 persons notified to be such in the two half-yearly returns, and that the same medical officer reported no inspection in 1904; and why, in view of these facts, he had not authorised an independent inspection at the expense of this borough under Section 4 of the Factory and Workshop Act, 1901.—Mr. Gladstone answered: I am aware of the figures referred to and I am communicating with the borough council on the subject. I am advised that it is doubtful whether the powers under Section 4 of the Factory Act cover a case such as this. But in any event for the Factory Department to assume in this and similar cases the duties in respect of home work which the Act imposes on local authorities would be to add greatly to the work of a department already more than fully employed. The whole question of home work is now under the consideration of a Select Committee of this House, and pending its report I cannot see my way to make the considerable change in the administration of these provisions which is suggested by the honourable gentleman.

Mr. Ramsay Macdonald, in the last of his series of questions to the Home Secretary, asked whether his attention had been drawn to the fact, as shown in Table 8 of the annual report of the Chief Inspector of Factories for 1906, that in 2194 cases, on the showing of medical officers of health, employers were discovered to have sent in to the district council no list of outworkers as provided by Section 107 of the Act, and that of these no fewer than 753 remained unremedied, a substantial increase being thus shown in the neglect in this respect over last year; whether his attention had also been drawn to the increased number of defects remaining unremedied as regards work being given out to be done in unwholesome premises, and allowing wearing apparel to be made in premises infected by scarlet fever or small-pox; and whether he could inform the House what steps the Home Office was taking to reduce the number of these cases of negligence on the part of so many medical officers of health.—Mr. Gladstone replied: I am aware of the figures to which the honourable Member calls attention. Taking the figures which relate to the outworkers' lists altogether, the returns for 1905 seem to me to point to an appreciable increase of activity on the part of local authorities with regard to the collection of these lists. 2500 more lists were received and 15,000 more names of outworkers and the fact that nearly 700 more failures were discovered than during the previous year shows, I think, that the officers of the local authority are following up these cases more carefully than before and perhaps also compiling the returns for the Home Office more carefully. I may call the attention of the honourable Member to the fact that the number of prosecutions taken by the local authorities for failure to send in lists is more than double that of 1904. As regards action under Sections 108 to 110 I do not think that any trustworthy inference can be drawn from the figures referred to in the question for the reasons mentioned in the introduction to last year's return. I have already stated in answer to a previous question the action taken by me with a view to improving the administration of the home work provisions of the Act by the local authorities.

Factory Inspection and Industrial Diseases.

Several interesting matters relating to such subjects as factory inspection and industrial diseases were raised when the House went into Committee of Supply on the vote of £153,735 for salaries and expenses in the Home Office.

Mr. Gladstone, the Home Secretary, opened the debate with a statement as to the work performed under the direction of his department. Referring to industrial diseases he said that box-wood poisoning had been added to the schedule of the Workmen's Compensation Act as an industrial disease. There had been a considerable increase in the number of cases of anthrax during the year and this had caused him a good deal of trouble. It was very difficult to find a reason for the increase of the disease. He had examined the statistics as to the amount of wool handled, and there seemed to be no relation between it and the number of cases of anthrax. However, the Home Office was doing everything in its power to investigate the subject, to stimulate inquiry, and to encourage the taking of precautions. A meeting of manufacturers and of officials of the department had been taking place to consider the whole question and had not yet terminated. He could only hope that science would suggest an absolute remedy for this terrible disease. At any rate, the department would do everything to devise methods to safeguard workmen. Then as to the question of poisoning by aniline and nitro and amido derivatives of benzene, a committee had sat to inquire into the matter; and such poisoning had been added to the schedule of the Workmen's Compensation Act. Proceeding, the right honourable gentleman said that at present the Home Office was conducting, or others were conducting on its behalf, many important inquiries. There were four Royal Commissions at work on subjects in which his department was particularly concerned—Commissions on Safety in Mines, on Vivisection, on the Metropolitan Police, and on the Care of the Feeble-minded. There were also a number of departmental committees at work. It was intended to start an inquiry into the conditions of labour in places where a high degree of humidity was combined with a high degree of heat. An inquiry which had taken place into an important accident in a match factory showed that the accident was due to causes which originated before the special regulations were brought into force. A return of accidents arising from poisoning was now available early in each year for the whole of the preceding year. The staff of factory inspectors at the Home Office consisted of 110 senior rank men, 13 lady inspectors, five inspectors for textile purposes, and 40 inspectors' assistants—a total of 168. There were 106,000 factories in the country, and it was thus clear that 168 persons, however zealous, could not possibly cover the multifarious duties cast upon them under the Factory and Workshop Act.

Sir Charles Dilke, in his speech, referred particularly to phosphorus poisoning in the match trade and to potter's diseases. With regard to phosphorus poisoning he said that the fact that the rules had to be revised showed that we had not reached a satisfactory position. The case as regarded lead poisoning was much stronger indeed. With regard to lead he regretted to find there had been a retrogression. He proceeded to deal with the disease known as potter's rot. After much consideration the departmental committee on compensation for industrial diseases arrived at the conclusion that it was a trade disease sufficiently distinguishable and specific to employment, but it could not recommend the immediate addition of the disease to the schedule. From the terms in which the report referred to this disease it appeared to him that there had been some change of intention at the last moment. The other potter's disease was lead poisoning, and it gave rise to horrible suffering. He was sorry to observe that the reports showed that there was now an increase of lead poisoning generally and that after there had been a considerable decrease. The cases which were the subject of reports passing through the Home Office in 1905 numbered 205, and in 1906 230. The number of cases of poisoning among women in white lead works was rising rapidly, as the statements of inspectors showed. There was a deplorable incidence of plumbism, among girls in particular, in the subsidiary processes, such as transfer making. There had been an increase in plumbism and of fatal cases in china and earthenware works and, horrible as was the suffering involved, the effect on the child population was worse, for there were an enormous infantile mortality and still-birth mortality due to the extensive employment of married women in the earthenware and china works, as the reports of the medical officers of health showed. The duty of the House was to see what could be done by administration and by law to improve this state of affairs. Certain minor defects were pointed out in the existing regulations and he imagined they had been, or would be, remedied. He alluded to such matters as the proper washing of over-alls and clothes and the removal of the moist conditions under which manufacture was sometimes carried on. The increase of lead-poisoning cases could not be explained away and the principal medical inspector dealing in his report with the preparation of hollowware used these terrible words: "All workers at this process become infected." Sir Charles Dilke went on to deal with the controversy as to the use of leadless glaze. Had not the Home Office, he asked, called for reports from Dr. Thorpe and Dr. T. Oliver, and had they not reported in favour of leadless glaze? Some of the Government departments, he regretted to say, did not now insist in their contracts that leadless glaze articles should be supplied to them.

Mr. Brace urged that if colliery owners did not provide themselves with rescue appliances and breathing apparatus for use in mine disasters within a reasonable time compulsion should be employed to make them do so.

Mr. Tennant pointed out that in some trades cases of poisoning had occurred from the inhalation of naphtha vapour, and he referred to a case which had been under treatment in the Glasgow Western Infirmary by Dr. Finlayson as an instance of the effect of the vapour on the internal organs. He urged that naphtha poisoning should be scheduled under the Workmen's Compensation Act as an industrial disease.

Mr. Herbert Samuel (the Under-Secretary of State to the Home Department) replied to various points which had been raised in the discussion. It was no doubt lamentable that the figures in lead poisoning again showed an upward tendency. Each case meant a terrible amount of human suffering and it was but a poor consolation most part it was an invention of the surgeon more given to enterprise than to exactness in diagnosis." In 1893 Mr. Morris, in the lecture already referred to, observed that "professional opinion was greatly divided as to the actual importance of moveable kidney; that whilst he and others believed it to be of serious import, one distinguished surgeon said that it was a myth, a thing of no pathological significance, and that a righteous scepticism ought to be entertained as to moveable kidney being the cause of real suffering." At a meeting of the Royal Medical and Chirurgical Society in April, 1893, during a discussion on this subject, Sir Thomas Smith said that many people had a loose kidney without experiencing any trouble from it.

Other authorities, while admitting its existence, and in some cases its importance, believe that it only occasionally calls for surgical interference. Hirst, in his "Text-book of Diseases of Women," published in 1902, says that out of considerably over 1000 female patients observed by him 200 had demonstrably displaced and mobile kidneys; only five of these, however, in his opinion, required nephrorrhaphy. Dr. Hare says that the subjects of this displacement often go for long years without any more formidable symptoms than a little dragging pain in the side, which requires little or no treatment In 1897 Baldy of Philadelphia said: "I do not hesitate to place myself on record as being entirely sceptical in regard to the whole subject of floating kidney. The large majority of the symptoms falsely attributed to the kidney can in all probability be attributed to the general neuroses from which these women suffer." On the other hand, such men as Newman of Glasgow, H. Morris, Kendal Franks, Keen, Goelet, Sturmdorf, Cumston, Longyear, Hutchinson, jun., McCosh, and Arbuthnot Lane all agree as to its great importance, and not only attribute to it certain very troublesome and serious symptoms but look upon it as the direct cause of such conditions as hydro- and possibly pyo nephrosis. Many consider that it is not merely a concomitant, but the real effective cause of the neuroses which have so often been observed in these cases. My own belief agrees with this.

The reason for so great a discrepancy in the estimation of the frequency of the condition is, I believe, to be found in two facts. The first is that some of the estimates were made in the post-mortem room. Now, rest in the supine position is one of the readiest means for reducing a dislocated kidney to its normal position; if, therefore, the cadaver before death had been, as would be most likely, for some time confined to this position the kidney would almost certainly be found after death normally placed; moreover, the perinephric fat, previously in a semi-fluid state, would have consolidated and so have apparently fixed the kidney. Estimates taken after death have therefore great inherent probabilities of fallacy. The other reason will be found in the variation which undoubtedly exists in the readiness with which the kidney can be displaced so that its malposition can be recognised from day to day in the same case. This is so well understood at present that few surgeons, I imagine, would care to base their opinion upon one single examination, unless the result were a definitely positive one.

But neither of these reasons will explain the very opposite views taken by physicians of the importance of this condition even when there is no question of its existence, nor indeed is it easy to reconcile them. What was true in 1893 and 1895 is practically as true to-day. On the one hand, many still look upon a floating kidney as only part, and that not a very important part, of a general neurasthenic state; whilst on the other, one well-known physician at least believes it responsible for acute melancholia, hypochondriasis, prolonged nervous exhaustion, constant ill-health and irritability of temper, periodic headaches, and dysmenorrhœa with vomiting and syncope, advising in all such cases that if a displaced kidney is found operation should at once be resorted to.

Probably the best, if not the only, explanation of this divergence will be found in this very neurotic element which is present in most of these cases. Most surgeons who have had much experience of operation upon neurasthenic patients before long learn to dread them. The results are never so satisfactory as they might confidently be expected to be in those who are free from this disturbing element; even if the particular symptoms of which the patient complained previously are removed they are only succeeded by a fresh set pointing in a different direction, so that the surgeon seems only to be beating the air—not at all the kind of exercise with which he desires his name to be associated. Such surgeons would be very prone to minimise the importance of any malposition or disturbance complained of by such patients, especially if the surgical means advised had been used by them and found to be non-effective.

But after all it has to be remembered that a neurotic patient is one whose nerves have been fretted out of her own control and that this fretting may be due to a variety of causes. Some of these may be entirely out of our province. Persistent family worries, family disputes, pecuniary difficulties, religious excitement, to mention no others, must be combated in other ways, but there remain some cases, and not a few, which are plainly due to physical causes, and of these none is more likely to be effective than a persistent or constantly recurring drag upon the nerves belonging to the sympathetic system, such as would be produced by a displaced kidney. If at the same time there were signs of recurrent distension of the sensitive kidney pelvis or renal substance, no one, I think, would deny that the only reasonable thing to do would be so to arrange matters that this recurrent drag upon nerves should be done away with, whilst at the same time any kinking of the ureter resulting in an obstruction to the outflow of urine should be straightened out and rendered innocuous.

In reference to this latter indication it is worth while to note that in the earlier stages of the descent of the kidney the attachment of the ureter at the side of the spinal column does not descend at the time or at the same rate as the body of the kidney itself; in many, if not all, cases this remains fixed for a considerable time after the lower pole of the kidney has described a curve which results in its lying much lower and nearer to the middle line than is its normal position. This produces of necessity an acute bend at the point where the pelvis of the kidney joins the ureter; urine at once tends to collect in the lower half of the pelvis, and although when the whole renal pelvis is full the intra-pelvic pressure may overcome the obstruction sufficiently to empty the upper half this pressure will be then so much reduced that the lower half will never entirely empty itself, and there remaining always some more or less stagnant urine in this portion of the cavity a certain amount of pyelitis is almost an inevitable consequence, more especially as to this must be added the effects of the new position upon the vessels supplying the kidney.

It is well known that when two vessels, one of them an artery, the other a vein, are subjected equally to pressure, kinking, or stretching, the calibre of the vein will suffer the most. Blood will still enter the organ affected long after it has ceased to pass out again with its accustomed freedom; the organ becomes congested; if the obstruction is too long-continued or too acute, some of the capillaries will give way and blood will be extravasated; the organ becomes correspondingly damaged, and thus a more ready prey to any micro-organism which may gain an entrance; all these conditions act and react upon one another and it becomes a mere matter of time and intensity as to when the organ in question will become useless or intensely dangerous to the general economy. If their due force is appreciated these reasons would appear sufficient to justify those who look upon actual displacement of the kidney, when this can be demonstrated, as a serious condition, one which in itself not only justifies but with some reservations actively calls for interference on the part of the surgeon. Before, however, discussing the form which such interference should take it will be well to review shortly the various ideas prevalent as to causation, since the view of the surgeon as to treatment will depend very largely upon his belief as to the causes which have produced the condition.

Certain writers attach great importance to the presence of the normal amount of fat in the fatty capsule surrounding the kidney as a means of maintaining the organ in its proper position and accordingly lay stress upon any previous disease accompanied by emaciation, looking upon this as a most efficient predisposing cause; consistently they advise measures which have as their object the increase of fatty deposit. This idea is not now generally accepted, since loose kidneys have been found to be present in persons with more than a fair share of adipose tissue, and operative work has demonstrated that a displaced kidney may coexist with a well-filled fatty capsule. Others claim that this displacement is only part of a general loosening of all the abdominal viscera—part, in fact, of Glénard's disease. This idea also has not stood the test of operative observation.

Much more importance must be attached to the far more whether his attention had been called to the case of a boy who died in Croydon on April 29th last as the result of vaccination, whether he was aware that the case was investigated by Dr. S. M. Copeman of the Local Government Board, that the child had sores on the head, face, and arms, and lingered in agony for three months, whether he would say if he was still supplying public vaccinators with the same class of lymph; and whether he would lay Dr. Copeman's report upon the table.—Mr. JOHN BURNS answered: I am aware of the case referred to, although I did not know that the child lingered in agony for three months, nor had I been informed of his death. The case was investigated by Dr. Copeman and several medical men. [illegible] other cases were vaccinated with the same lymph as this child and, so far as was ascertained, the case in question was the only one in which the child subsequently had sores. These sores appear to have been, in fact, "the bromide rash" and to have been due not to vaccination but to doses of bromide of potassium administered by the mother on account of the fits from which the child suffered. It is estimated that [illegible] grains of the drug were given to him. Dr. Copeman's report is a confidential document and I could not undertake to lay it on the table of the House.

Medical Officers and the Factory Act.

Mr. RAMSAY MACDONALD asked the Secretary of State for the Home Department whether his attention had been drawn to Table I in the report of the Chief Inspector of Factories for 1906, wherein it was shown that the number of names of outworkers received was greatly in excess of the number of visits made by the medical officers of health in Sheffield, Bolton, Worcester, Ipswich, Gloucestershire, West Ham, [illegible], and other areas, and what steps he proposed to take to make this inspection efficient.—Mr. GLADSTONE said in answer: Yes, sir, this table was included in the chief inspector's report by my directions with a view to the improvement of the present conditions. The steps that have been taken by me to improve the administration of the home work provisions of the Factory Act by the local authorities have been to issue a circular on the subject to the authorities and the medical officers of health, calling their attention to the importance of a thorough administration of the Act and secondly, to propose that the matter shall be discussed at a conference with medical officers of health which it is intended to hold at the Home Office in the autumn.

Mr. RAMSAY MACDONALD then asked the right honourable gentleman whether his attention had been drawn to the fact, as shown in the annual report of the Chief Inspector of Factories for 1906, that [illegible] medical officers of health still neglected to perform the statutory duties imposed on them by the Factory and Workshop Act to report to the Home Office regarding their administration of that Act, and how long the Home Office proposed to allow this neglect to continue.—Mr. GLADSTONE replied: The great majority of the medical officers who have failed to send in reports—namely, [illegible] out of [illegible]—are in Ireland. Under the Irish Public Health law the medical officers other than the few superintending medical officers are not required to make any report to the local authority and I am advised that it is doubtful how far in consequence any obligation is placed upon them by Section 132 of the Factory Act. As I have already stated, a special circular was sent out last year by the Home Office calling the attention of the local authorities and medical officers to their duties in regard to home work, and I propose to communicate specially this autumn with those local authorities from which no reports were received in 1906. I may add that in many districts from which no report is sent the Factory Act has little or no application, and the omission is comparatively unimportant.

Mr. RAMSAY MACDONALD put a further question to the Home Secretary as to whether his attention had been drawn to the figures in the annual report of the Chief Inspector of Factories, showing that in 1905 in the borough of Stepney the medical officer reported only [illegible] inspections of outworkers out of [illegible] persons notified to be such in the two half-yearly returns, and that the same medical officer reported no inspections in 1906; and why, in view of these facts, he had not authorised an independent inspection at the expense of this borough under Section [illegible] of the Factory and Workshop Act, 1901.—Mr. GLADSTONE answered: I am aware of the figures referred to and I am communicating with the borough council on the subject. I am advised that it is doubtful whether the powers under Section 4 of the Factory Act cover a case such as this. But in any event for the Factory Department to assume in this and similar cases the duties in respect of home work which the Act imposes on local authorities would be to add greatly to the work of a department already more than fully employed. The whole question of home work is now under the consideration of a Select Committee of this House, and pending its report I cannot see my way to make the considerable change in the administration of these provisions which is suggested by the honourable gentleman.

Mr. RAMSAY MACDONALD, in the last of his series of questions to the Home Secretary, asked whether his attention had been drawn to the fact, as shown in Table 8 of the annual report of the Chief Inspector of Factories for 1906, that in [illegible] cases on the showing of medical officers of health, employers were discovered to have sent in to the district council no list of outworkers as provided by Section 107 of the Act, and that of these no fewer than [illegible] remained unrectified, a substantial increase being thus shown in the neglect in this respect over last year; whether his attention had also been drawn to the increased number of defects remaining unremedied as regards work being given out to be done in unwholesome premises, and wearing apparel to be made in premises infected by scarlet fever or small-pox; and whether he could inform the House what steps the Home Office was taking to reduce the number of these cases of negligence on the part of so many medical officers of health.—Mr. GLADSTONE replied: I am aware of the figures to which the honourable Member calls attention. Taking the figures which relate to the outworkers' lists altogether, the returns for 1906 seem to me to point to an appreciable increase of activity on the part of local authorities with regard to the collection of these lists. [illegible] more lists were received and [illegible] more names of outworkers and the fact that [illegible] more failures were discovered than during the previous year shows, I think, that the officers of the local authority are following up these cases more carefully than before and perhaps also compiling the returns for the Home Office more carefully. I may call the attention of the honourable Member to the fact that the number of proceedings taken by the local authorities for failure to send in lists is more than double that of 1905. As regards action under Sections 108 to 110 I do not think that any trustworthy inference can be drawn from the figures referred to in the question for the reasons mentioned in the introduction to last year's returns. I have already stated in answer to a previous question the action taken by me with a view to improving the administration of the home work provisions of the Act by the local authorities.

Factory Inspection and Industrial Diseases.

Several interesting matters relating to such subjects as factory inspection and industrial diseases were raised when the House went into Committee of Supply on the vote of £[illegible] for salaries and expenses in the Home Office.

Mr. GLADSTONE, the Home Secretary, opened the debate with a statement as to the work performed under the direction of his department. Referring to industrial diseases he said that box wood poisoning had been added to the schedule of the Workmen's Compensation Act as an industrial disease. There had been a considerable increase in the number of cases of anthrax during the year and this had caused him a good deal of trouble. It was very difficult to find a reason for the increase of the disease. He had examined the statistics as to the amount of wool handled, and there seemed to be no relation between it and the number of cases of anthrax. However, the Home Office was doing everything in its power to investigate the subject, to stimulate inquiry, and to encourage the taking of precautions. A meeting of manufacturers and of officials of the department had been taking place to consider the whole question and had not yet terminated. He could only hope that science would suggest an absolute remedy for this terrible disease. At any rate, the department would do everything to devise methods to safeguard workers. Then as to the question of poisoning by aniline and nitro and amido derivatives of benzene, a committee had sat to inquire into the matter; and such poisoning had been added to the schedule of the Workmen's Compensation Act. Proceeding, the right honourable gentleman said that at present the Home Office was conducting, or others were conducting on its behalf, many important inquiries. There were four Royal Commissions at work on subjects in which his department was particularly interested—Commissions on Safety in Mines, on Vivisection, on the Metropolitan Police, and on the Care of the Feeble-minded. There were also a number of departmental committees at work. It was intended to start an inquiry into the conditions of labour in places where a high degree of humidity was combined with a high degree of heat. An inquiry which had taken place into an important accident in a match factory showed that the accident was due to causes which originated before the special regulations were brought into force. A return of accidents arising from poisoning was now available early in each year for the whole of the preceding year. The staff of factory inspectors at the Home Office consisted of [illegible] senior rank men, [illegible] lady inspectors, five inspectors for textile purposes, and [illegible] inspectors' assistants—a total of [illegible]. There were [illegible] factories in the country, and it was thus clear that [illegible] persons, however zealous, could not possibly cover the multifarious duties cast upon them under the Factory and Workshop Act.

Sir CHARLES DILKE, in his speech, referred particularly to phosphorus poisoning in the match trade and to potter's diseases. With regard to phosphorus poisoning he said that the fact that the rules had to be revised showed that we had not reached a satisfactory position. The case as regarded lead poisoning was much stronger indeed. With regard to lead he regretted to find there had been a retrogression. He proceeded to deal with the disease known as potter's rot. After much consideration the departmental committee on compensation for industrial diseases arrived at the conclusion that it was a trade disease sufficiently distinguishable and special to employment, but it could not recommend the immediate addition of the disease to the schedule. From the terms in which the report referred to this disease it appeared to him that there had been some change of intention at the last moment. The other potter's disease was lead poisoning, and it gave rise to horrible suffering. He was sorry to observe that the reports showed that there was now an increase of lead poisoning generally and that after there had been a considerable decrease. The cases which were the subject of reports passing through the Home Office in 1905 numbered [illegible], and in 1906 [illegible]. The number of cases of poisoning among women in white lead works was rising rapidly, as the statements of inspectors showed. There was a deplorable incidence of plumbism among girls in particular, in the subsidiary processes, such as transfer making. There had been an increase in plumbism and of fatal cases in china and earthenware works and, horrible as was the suffering involved, the effect on the child population was worse, for there were an enormous infantile mortality and still-birth mortality due to the extensive employment of married women in the earthenware and china works, as the reports of the medical officers of health showed. The duty of the House was to see what could be done by administration and by law to improve this state of affairs. Certain minor defects were pointed out in the existing regulations and he imagined they had been, or would be, remedied. He alluded to such matters as the proper washing of overalls and clothes and the removal of the [illegible] conditions under which manufacture was sometimes carried on. The increase of lead-poisoning cases could not be explained away and the principal medical inspector dealing in his report with the preparation of hollow-ware used these terrible words: "All workers at this process become infected." Sir CHARLES DILKE went on to deal with the controversy as to the use of leadless glaze. Had not the Home Office, he asked, called for reports from Dr. Thorpe and Dr. T. Oliver, and had they not reported in favour of leadless glaze? Some of the Government departments, he regretted to say, did not now insist in their contracts that leadless glaze articles should be supplied to them.

Mr. BRACE urged that if colliery owners did not provide themselves with rescue appliances and breathing apparatus for use in mine disasters within a reasonable time compulsion should be employed to make them do so.

Mr. [illegible] pointed out that in some trades cases of poisoning had occurred from the inhalation of naphtha vapour, and he referred to a case which had been under treatment in the Glasgow Western Infirmary by Dr. [illegible] as an instance of the effect of the vapour on the internal organs. He urged that naphtha poisoning should be scheduled under the Workmen's Compensation Act as an industrial disease.

Mr. HERBERT SAMUEL (the Under-Secretary of State to the Home Department) replied to various points which had been raised in the discussion. It was no doubt lamentable that the figures in lead poisoning again showed an upward tendency. Each case meant a terrible amount of human suffering and it was but a poor consolation so that the kidney obtains at last so much freedom of movement that it may be found in the iliac fossa or in almost any part of the corresponding side of the abdomen. Diagnosis by means of manual examination is now easy, whilst the symptoms observed are different in character and are generally less acute. Kinking of the ureter is much less likely to occur and, if it does, is much more easily overcome by the *vis a tergo* of the urinary stream. The symptoms are still the same in name but not in character. Pain is no longer sudden and acute, there is rather a feeling of weight and discomfort in one loin or spreading downwards into the groin on the same side, with a sensation of dragging, and there are stiffness in the back, some cramp in the abdomen, sensations which may simulate fœtal movements, and backache. All these symptoms will be increased by exercise, by standing or running, and will be relieved, almost certainly, by rest in the supine position. The most uncomfortable pose will be that of lying upon the sound side. Digestive disturbances are common in this stage, but they tend to take the form of chronic or intermittent dyspepsia, coming on without any cause in the shape of improper diet. Apnœa or pseudo-anginal attacks may also be noticed when the lesion occurs on the left side, apparently being due to traction upon the pericardium through the diaphragm. It is perhaps in this stage also that neurasthenia and hysteria are most often seen. In order to reach this stage the patient must have passed through many weary months of apparently unexplainable discomfort—the persistently recurring drag upon the renal attachments, upon the renal plexus, and through it upon the solar plexus; the opening up of the post-peritoneal planes of connective tissue with its resultant loss of support to the colon, this latter in its turn favouring constipation and the sapræmia which is one of its consequences; all these may well act and react upon one another until at last the half-poisoned and therefore greatly weakened nervous system, persistently fretted, loses its tone and with it all power of controlling hysteric manifestations.

In both stages there may be present a complicating factor which fortunately is only occasionally seen; this is the presence of phosphatic or other calculous deposit in the renal pelvis or ureter. Should such deposit be present it will naturally greatly intensify the pain felt; it probably stands rather in the position of an effect than of a cause of the digestive disturbances; its relation to hysteria is still more doubtful.

So far only the symptoms of this condition have been considered, but the differentiation of it from other states with which it might be confused must now be briefly dealt with.

The pain and dragging in the right loin are the things of which the patient most often first complains. These usually precede Dietl's crises and, therefore, there is usually a history, if it can be obtained, of such symptoms extending over an indefinite time. Sometimes the patient will refer the commencement of her discomfort to an injury. No doubt a sudden injury to the loin may act as a cause in some cases; one of my patients believed that a slip off a step-ladder which brought her side suddenly in contact with the edge of a table was the starting-point; Newman mentions a similar case. Although it would be impossible to deny this still previous experience will convince any one who is alive to the fact of the great tendency of patients generally to put down to accidents, however long the interval that may have elapsed, all unexplainable symptoms from which they may afterwards suffer and this is especially the case with neurasthenics. In a search which the writer undertook some years ago with reference to the etiology of chronic hernia he came across persons who attributed their disability to accidents which had happened 20 years before the appearance of any weakness in the abdominal wall and it was only on a close cross-examination that this interval was admitted, the first statement of the patient suggesting that the accident had immediately preceded the rupture. So also it often is with other complaints, mobile kidney among the rest. Statements of this kind should always be received with caution. Dietl's crises may suggest the passage of a gall-stone through the biliary ducts, or a urinary calculus through the ureter; they may also simulate attacks of appendicitis. The first may be eliminated by the absence of a positive reaction to Murphy's test; the second, by the fact that the pain is not usually referred to the external genitals and by the absence of any blood or crystalline deposits in the urine; the last by the absence of a rise of temperature, by the absence of pain in the right iliac fossa and rigidity of the lower end of the right rectus and oblique muscles. But the actual diagnosis will at the last depend upon the power of the examiner to detect any movement of the kidney itself. Three methods are recommended by means of which this may be done.

1. *Glénard's method.*—The lower part of the thorax is compressed by placing the fingers of the examiner's left hand just below the eleventh rib posteriorly and the thumb of the same hand on the level of, and internal to, the chondral extremity of the ninth rib in front, the other hand, placed on the umbilical region, crowding back the abdominal walls; the first hand thus forms a narrow ring, completed on its inner side posteriorly by the vertebral column and anteriorly by the fingers of the other hand.

2. *Israel's method.*—The patient lies on the sound side; the examiner stands on the left side of the couch to examine the right kidney and *vice versâ*. For the right kidney he places the fingers of the left hand on the right lumbar region and the right hand on the anterior abdominal wall, so that the tips of the index and middle fingers are two fingers' breadth below the junction of the ninth and tenth costal cartilages. The patient takes a deep inspiration and the kidney is felt at the end of this act.

3. *Morris's method.*—The patient lies flat on her back, with the shoulders slightly raised and the lower limbs slightly flexed; she lies close to the right side of the couch for the examination of the right kidney, to the left side of the couch for the left kidney, the examiner stands or sits on the same side as that of the organ he is examining, and grips the loin between the two hands; with that on the back the lumbar parietes are firmly pressed forwards, while the fingers of the hand in front gently and steadily depress the anterior abdominal walls upwards, backwards, and inwards. The patient is directed to take a long-drawn sigh, the front hand follows the receding wall relaxed by expiration; if not successful the sighs are to be repeated. This method is sometimes assisted by raising the patient's shoulders so that she assumes the semi-recumbent attitude, or by rolling her over to the opposite side. The kidney is best felt at the end of inspiration and at the very beginning of expiration.

Of these methods it is difficult to say which is the best, sometimes one method will succeed, sometimes another. One point, I think, is worth adding, whichever method is used—and they do not greatly differ—the fingers of the hand placed in front should be allowed time enough to enable them gently and slowly to sink until they come into contact with the anterior surface of the spinal column; still keeping in contact with it, the hand is so turned that its palm looks upwards and outwards, the tips of the fingers slide downwards and upwards along the side of the vertebræ until they feel the posterior wall of the abdominal cavity; if now the other hand is made to grip the loin the fingers of the anterior will feel those of the posterior hand, whilst the thumb of the latter will complete the ring so formed below and around the kidney; in this way it will be possible to assure oneself that the kidney is not already prolapsed, since were this so the anterior fingers must have come in contact with it during their descent, and nothing can now pass downwards without detection. The point I believe on which it is well to lay stress is the identification of the spinal column by the fingers of the anterior hand before any effort at inspiration is made by the patient. In this way the examiner is not only made aware of his exact locality, but can differentiate movement behind the posterior peritoneum which can only be due to kidney, from movements above which might be due to omental, biliary, or intestinal masses of various kinds. Of course, in practised hands, the shape, size, and peculiar feel of the kidney are easily identified, but to novices these characteristics might not be so clear. Very often the displacement can be most readily detected when the patient is in the upright position.

When the question of the treatment of "wandering" kidney is considered, as many differences of opinion are encountered in this as in those already discussed, and at the present time none of the methods in vogue can be said to be universally accepted. As a matter of course, external appliances which, by their position and the direction in which the force they could be made to exert will act, would restrain the movements of the loosened organ or supply the support which had been lost were used at first, and it was only when these were found to be inefficient that operative means were sought. Trusses of various kinds, belts, aware that the estimates given by the Indian Statistical Department of the plague victims in the year 1904 varied between highest and lowest in round figures 200,000; and whether he would look into the administration of this department with a view to the matter presented for publication being made intelligible and consistent.—Mr. MORLEY replied: The extreme variation to which my honourable friend calls attention is due to the fact that the higher figure refers to the whole of India, including Native States, and the lower one to British India only. The figure which I quoted in replying to a question on July 8th was taken from a special return recently published by the Government of India and differs from the figure given in its annual sanitary report, from which the statistics given in the Moral and Material Progress Report and the Statistical Abstract are taken. I have asked for an explanation of the discrepancy.

The Prevention of Cruelty to Children Bill.

Mr. COURTHOPE asked the Prime Minister whether, in view of the death-rate amongst young children from burning and overlying, he would afford facilities for the passage into law of the Prevention of Cruelty to Children Bill during the present session.—Sir HENRY CAMPBELL-BANNERMAN answered: The time has not yet come to decide on the Bills for which facilities will be given. I believe this Bill has not yet received a second reading.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.*

BONNEY, VICTOR, M.S., M.D. Lond., F.R.C.S., M.R.C.P., has been appointed Hunterian Professor at the Royal College of Surgeons of England.

BOYCOTT, A. E., M.D., B.S. Oxon., has been appointed Gordon Lecturer on Pathology at Guy's Hospital.

COLLIE, R. J., M.D., C.M. Aberd., has been appointed a Medical Referee under the Workmen's Compensation Act, 1906, to be attached to County Court Circuit No. 43.

COPE, V. ZACHARY, M.D., B.S. Lond., has been appointed Resident Medical Officer at the British Lying-in Hospital.

KERR, HAROLD, M.D., Ch.B. Edin., D.P.H. Camb., has been appointed Assistant Medical Officer of Health of the City of Newcastle-upon-Tyne.

JONES, RICHARD, M.B., M.S. Edin., D.P.H. Camb., has been appointed Medical Referee under the Compensation Act for the County Court Circuit of Blaenau Festiniog and Portmadoc.

LESLIE, W. MURRAY, M.D., M.S. Edin., has been appointed Medical Referee under the Workmen's Compensation Act in the City of London.

MACMYN, J., M.D., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Kirkcudbright District of the county of Kirkcudbright.

PAUL, V. G. J., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Harwich District of the county of Essex.

PEARSE, T. F., M.D. Brux., F.R.C.S. Eng., M.R.C.P. Lond., D.P.H., has been appointed Health Officer to the Corporation of Calcutta.

STEELL, GRAHAM, M.D. Edin., F.R.C.P. Lond., has been appointed Professor of Medicine in the University of Manchester.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM WORKHOUSE INFIRMARY.—Assistant Resident Medical Officer. Salary £104 per annum, with apartments, rations, &c.

BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £100.

BRADFORD POOR LAW UNION HOSPITAL AND WORKHOUSE.—Resident Assistant Medical Officer, unmarried. Salary £100, with rations, apartments, and washing.

BRIGHTON AND HOVE HOSPITAL FOR WOMEN.—House Surgeon, unmarried. Salary £80 per annum, with apartments, board, gas, coal, and attendance.

CAIRO, SCHOOL OF MEDICINE (EGYPTIAN GOVERNMENT, MINISTRY OF EDUCATION).—Assistant to the Professor of Pathology. Salary £E.320 per annum.

CAMBRIDGE, CAMBRIDGESHIRE LUNATIC ASYLUM, Fulbourn.—Second Assistant Medical Officer, unmarried. Salary £120 per annum, with board, lodging, and attendance.

CANCER HOSPITAL, Fulham-road, London, S.W.—Two Assistant Anæsthetists. Honorarium of 25 guineas each.

CARDIFF INFIRMARY (GENERAL HOSPITAL).—House Physician for six months. Salary £50, with board, residence, and laundry.

CARMARTHENSHIRE INFIRMARY.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, attendance, &c.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician, for six months. Salary at rate of £50 per annum, with board, washing, and residence.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon for six months. Salary £60 per annum, with rooms, board, washing, and attendance.

DEVON COUNTY ASYLUM.—Assistant Medical Officer. Salary £140, with board, apartments, and laundry.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, &c.

"DREADNOUGHT" HOSPITAL, Greenwich.—Pathologist. Salary £100 per annum.

EGYPT, PUBLIC HEALTH DEPARTMENT.—Sub-[illegible] of Ophthalmic Hospitals.

GLOUCESTER, GENERAL INFIRMARY AND THE GLOUCESTERSHIRE EYE INSTITUTION.—Assistant House Surgeoncy for six months. Salary at rate of £30 per annum, with board, residence, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician. House Surgeon. Assistant Casualty Officer.

HULL, ROYAL INFIRMARY.—Casualty House Surgeon. Salary £50, with board and lodging.

IPSWICH, EAST SUFFOLK AND IPSWICH HOSPITAL.—Third House Surgeon. Salary £50 per annum, with board, attendance, and washing.

KENSINGTON GENERAL HOSPITAL, Earl's Court, London, S.W.—Junior Resident Medical Officer for six months. Salary £40 per annum, with board, washing, and residence.

LANCASTER, ROYAL LANCASTER INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, attendance, and washing.

LINCOLN COUNTY HOSPITAL.—Junior House Surgeon, unmarried, for six months. Salary £30, with board, residence, and washing.

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Resident Pathologist and Registrar. Salary £100, with board and residence.

LONDON UNIVERSITY.—Roger's Prize, 1908.

LOUGHBOROUGH AND DISTRICT GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon. Salary £100 a year, with rooms, attendance, board, and washing.

METROPOLITAN ASYLUMS BOARD FEVER HOSPITALS SERVICE.—Assistant Medical Officers, unmarried. Salary £150, rising to £240 per annum, with board, lodging, and washing.

MICKLEOVER, DERBY COUNTY ASYLUM.—Junior Assistant Medical Officer. Salary £120, rising to £150 per annum, with apartments, board, washing, and attendance.

NORFOLK AND NORWICH HOSPITAL.—House Surgeon. Salary £80 per annum, with board, lodging, and washing. Also Two Assistant House Surgeons for six months. Salary £20, with board, lodging, and washing.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Physician for six months. Salary at rate of £80 per annum, with board, residence, and laundry.

NORWICH, JENNY LIND INFIRMARY FOR CHILDREN, Unthank-road.—Resident Medical Officer (female). Salary £50 per annum, with board, residence, and laundry.

PAISLEY, INFECTIOUS DISEASES HOSPITAL.—Assistant Medical Officer. Salary £100 per annum, with board, washing, and attendance.

PERTH ROYAL INFIRMARY.—House Surgeon. Salary £60, with board.

PLAISTOW FEVER HOSPITAL, London, E.—Second Assistant Medical Officer for six months. Salary at rate of £100 per annum, with board, &c.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Physician for six months, renewable. Salary £50, with board, residence, and washing.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone road, N.W.—Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

ROCHDALE AND DISTRICT DEAF AND DUMB SOCIETY.—Missioner.

ROYAL DENTAL HOSPITAL, Leicester-square.—Morning House Anæsthetist. Salary £50 per annum.

ROYAL EYE HOSPITAL, St. George's-circus, S.E.—Refraction Assistant. Salary £40 per annum. Also Clinical Assistants.

SALFORD ROYAL HOSPITAL.—Junior House Surgeon. Salary at rate of £50 per annum, with board and residence.

SOUTHPORT INFIRMARY.—Residents' Senior House Surgeon. Also Junior House and Visiting Surgeon, unmarried, for six months. Salary of Senior at rate of £90 per annum, and of Junior £70 per annum, with residence, board, and washing.

STAFFORD, STAFFORDSHIRE COUNTY ASYLUM.—Assistant Medical Officer, unmarried. Salary £150, rising to £200, with apartments, board, and washing.

STOCKPORT INFIRMARY.—House Surgeon. Salary £100 per annum, with board, washing, and residence. Also Assistant House and Visiting Surgeon. Salary £80 per annum, with board, washing, and residence.

SUNDERLAND INFIRMARY.—House Physician and Pathologist, also House Surgeon. Salary in each case £80 per annum, with board, residence, and washing.

TAUNTON, TAUNTON AND SOMERSET HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry. Also Resident House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

TEIGNMOUTH HOSPITAL, South Devon.—House Surgeon. Salary £70 a year, with board, lodging, and washing.

WESTERN GENERAL DISPENSARY, Marylebone-road, N.W.—Honorary Anæsthetist.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—Resident House Surgeon. Salary £120 a year, with board and lodging.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £120 a year, with board, lodging, and attendance.

ZANZIBAR GOVERNMENT.—Bacteriologist. Salary £300 a year, rising to £400, with free quarters, &c.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Market Harborough, in the county of Leicester.

Births, Marriages, and Deaths.

BIRTHS.

GEDDES.—On July 20th, at Redhouse, South Gillsland-road, Edinburgh, the wife of A. Campbell Geddes, M.B., of a son.

MACDONALD.—On July 18th, at Argyll-square, Oban, the wife of Duncan MacDonald, M.D. & C.M., of a son.

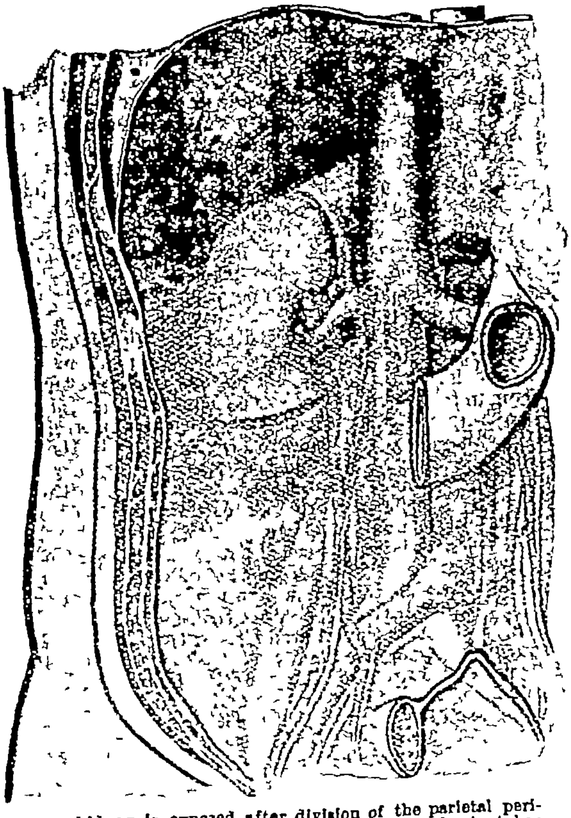
DEATHS.

HODGE.—On July 21st, at Kuling, China, the Rev. Sydney Rupert Hodge, M.R.C.S., L.R.C.P., aged 48.

STOCKER.—On July 18th, at Hillingdon, John Sherwood Stocker, M.D. Lond., M.R.C.P.

methods there is no more danger in the one than in the other route, and in order to carry out all the indications to which I have referred it is necessary to attack the organ from the front. The incision I have found most useful is that advocated by Rutherford Morison in cases of cholecystotomy; an obliquely transverse incision through the muscles of the abdominal wall outside the rectus muscle, the feasibility and harmlessness of which have thus been demonstrated. This incision gives free access to the renal fossa on the right side, and renders all succeeding steps in this, the anterior fixation of the kidney, easy and practicable. It was, indeed, the use of this incision in biliary cases which suggested to me its capability for utilisation for the operation for renal support. If this oblique incision is carried from a point corresponding to the chondral tip of the tenth rib, or what is the same thing, from the outer edge of the rectus muscle backwards to a point midway between the sternum and the spine, on a level one inch below the border of the rib, admirable access is gained to the renal fossa, and all further steps present no difficulty. From this point I shall only describe the operation on the right side, which is the side most frequently affected. The liver being lifted, the stomach drawn inwards, and the hepatic flexure of the colon depressed out of the way by broad retractors or large flat sponges the kidney can easily be felt and seen beneath the posterior peritoneum. And not only the kidney but, in the majority of cases, the renal veins also. In the displaced position of the kidney these veins are seen through the semi-transparent peritoneum, lying obliquely with their renal extremities much lower than the spinal. When the kidney is pushed up they can be seen to glide upwards and to become transverse, and so they form a good guide, not only to the correct position of the kidney, the position in which it should be fixed, but also to the point of entrance of the first fixating suture.

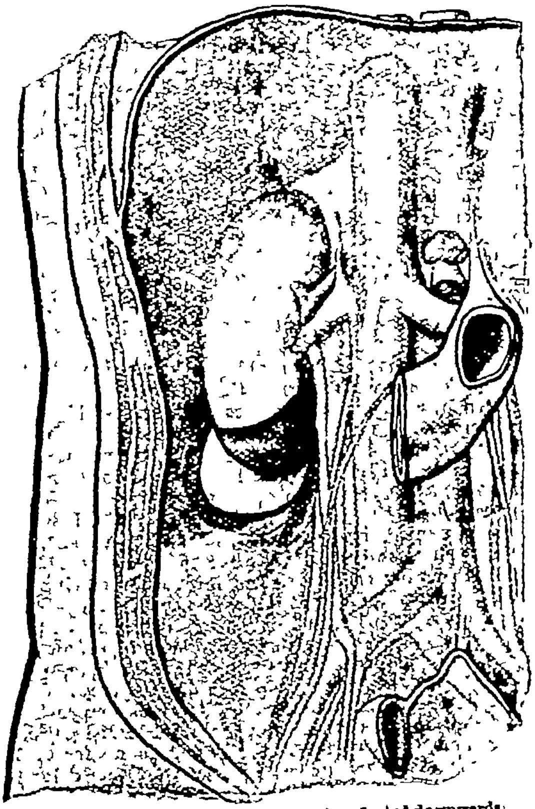
FIG. 1.



The kidney is exposed after division of the parietal peritoneum. The curved incision described in the text has been made in the lower part of the kidney capsule.

The parietal peritoneum is now divided transversely over the lower fourth of the kidney; the two peritoneal edges being held apart, a curved incision, concave upwards and outwards, is made in the proper capsule (Fig. 1), and the lower segment of this loosened from the anterior renal surface down to its inner and lower extremity; this capsule remains, of course, attached to the posterior surface of the organ; its flap is turned downwards and inwards, leaving the raw surface of the kidney exposed for a corresponding distance (Fig. 2); two or three sutures attach this loosened edge of the capsule to the fascia beneath; the peritoneum is again sewn up by catgut; the anterior surface of the lower leaflet of the true capsule is now in contact with the posterior abdominal wall, and the posterior surface of the peritoneum is lying upon it and upon the bared lower anterior renal tissue (Fig. 3).

FIG. 2.



The lower flap of the kidney capsule is reflected downwards, leaving the raw surface of the kidney exposed.

The correct position of the kidney being now accurately determined it is held there by the three outer fingers of the left hand, whilst the left forefinger is placed on the inner side immediately below the ureteric insertion. A long straight needle, armed with a long thread of iodised or chromicised catgut, No. 3, is pushed directly backwards at this point until its point emerges behind; another needle, carrying the opposite end of the same thread, is pushed through in the same manner one centimetre below the first; when both needles are drawn through (Fig. 4) the thread is tied over the muscular layer behind the peritoneum, capsule, and posterior tissues are united on the inner side of the lower pole of the kidney; another pair of needles are placed in a similar manner so as to carry a loop of catgut below the inner lower angle; two or three more pairs carry loops below the kidney, and, if deemed necessary, around the lower and outer side of the organ; all these pass through peritoneum, capsule, subperitoneal connective tissue and muscles; when these are all drawn tight and tied it will be seen that the kidney is supported by a row of sutures which do not penetrate its substance but effectually fix it and close the cavity beneath it, whilst the union of the capsule and peritoneum has formed a somewhat stronger Toldt's fascia than normally exists on the opposite side. Any communicating fibres between the kidney and the colon are now pinned down to the posterior abdominal wall, to which henceforth any downward pull is transferred. The skin may now be divided behind between the protruding needle points, and this incision carried down to the muscular layer over which each suture is tied; or, as I have found to

FRIDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. FRIDAY (2nd).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. X Rays. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

SATURDAY (3rd).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. X Rays. 2.30 P.M.: Operations. Dr. Robinson: Diseases of Women.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1907, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in THE LANCET of July 6th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1907 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

During the week marked copies of the following newspapers have been received:—*Welsh Pioneer, Manchester Guardian, Glossopdale Chronicle, Townsville Daily Bulletin (Queensland, Australia), Belfast News Letter, Northern Whig (Ireland), Liverpool Courier, Birmingham Post, Bristol Mercury, Leeds and Yorkshire Mercury, Freeman's Journal, Dublin Times, Hull Mail, Dublin Independent, Leeds Post, Sheffield Independent, Leicester Post, Westminster Gazette, &c.*

A STUDY OF THE CONDITIONS PRODUCING THE ANOMALOUS REACTION NOT INFREQUENTLY MET WITH ON TESTING URINE FOR SUGAR WITH FEHLING'S SOLUTION.

BY F. W. PAVY, M.D. LOND., LL.D., F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL; HONORARY PHYSICIAN TO KING EDWARD VII. HOSPITAL.

(Continued from p. 227.)

INFLUENCE OF CREATININE ON THE REACTION BETWEEN FEHLING'S SOLUTION AND SUGAR.

As yet I have only spoken of the interaction that takes place between creatinine and Fehling's solution. Let us now see what effect is exerted by the presence of creatinine upon the reaction produced between Fehling's solution and sugar. If much sugar is present a full reaction immediately occurs, the amount of suboxide produced being beyond the power of the creatinine to check its being deposited. If, on the other hand, only a small amount of sugar is present the reaction assumes a modified character and the smaller the amount the greater the extent of modification that ensues. The first effect noticeable is some fading of the blue colour, the liquid remaining clear, and if the amount of sugar should be sufficient to *reduce fully* the Fehling's solution used, and the amount of creatinine present sufficient to inhibit for the requisite length of time *precipitation* of the reduced oxide, the liquid will attain a colourless state before the precipitation stage of the reaction is reached. Everything depends upon the relative amounts of sugar and creatinine present, and consequently, according to the conditions existing in these respects, so will be the result that occurs.

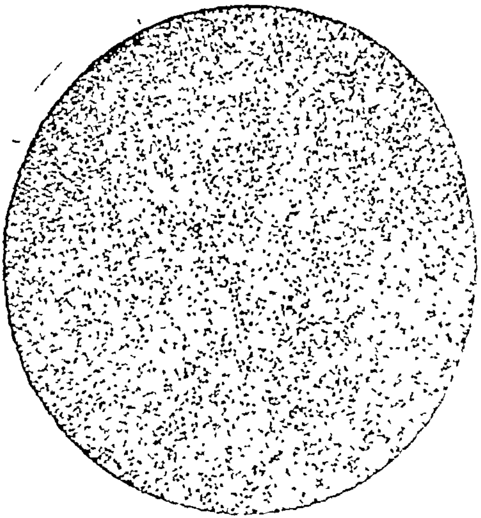
If close attention be given to the phenomena that take place it is noticeable that two distinct events have to be dealt with. The one is the production of an altered kind of precipitate; the other is the inhibition of suboxide precipitation by the agency of solvent action. I will take them for consideration in the order they have been mentioned.

Production of an altered kind of precipitate.—Microscopic examination tells us that the physical condition of the suboxide precipitate produced by the action of sugar upon Fehling's solution is *very different* when creatinine is present from that of the precipitate produced when sugar and Fehling's solution are alone dealt with. As I have already stated, the precipitate which falls in the latter case is seen on microscopic examination to consist of fairish-sized nodules which have a strong agglutinating tendency and cohere into irregular-shaped clusters. They are shown at Fig. 1 inserted in a former part of this communication. The precipitate which falls in the presence of creatinine presents itself in the form of very minute particles more or less devoid of coalescing tendency, so that the field is strewed, as is shown in Fig. 5, with isolated particles after the manner of what is seen in the case of an emulsion and, when in an exceedingly fine state from the employment of a full quantity of creatinine, looking, as previously mentioned, like the molecular base of chyle.

Creatinine, then, has the effect of interfering with the coalescence of the precipitated suboxide as it is thrown out of solution. A condition exists comparable to that of an emulsion, which may be defined as consisting of small non-coalescing particles suspended in a liquid. There are emulsifying agents or agents possessing the property of giving rise to the passage of matter into a finely divided state and keeping it in this state by annulling the exercise of surface attraction power—a power which I may speak of in passing as standing at the foundation of a vast number of the phenomena taking place around us—a power which constitutes the determining factor in connexion with, for instance, capillary attraction, the wetting or resistance to wetting of substances, the selective absorption by charcoal, the taking or not taking of stains, and adsorption which counterfeits the selective action of living matter—a power which represents affinity without actual chemical union and which, unlike affinity, has *not* yet received the systematic consideration as a power that it appears to me to deserve.

Considerable attention has been given to the subject of emulsification viewed *in relation to the operative* influence existing. I need not enter into the questions that have been raised. Suffice it for my purpose to say that *something* is brought into play which *interferes* with the exercise of the attractive power that, otherwise circumstanced, leads to coalescence. Creatinine in the case under *consideration* gives to the environment of the falling suboxide precipitate a *property* which prevents the newly *formed* product from coalescing into aggregated masses. Thus, when full *force* is in play the product may present itself in so minutely divided a state as to be *only* just within the range of visibility with the magnifying power of the microscope, or, on the other hand, beyond the power, it may be assumed, of distinct perception, as when a pale-coloured, opalescent state exists. When in *actual* solution a colourless watery liquid is obtained.

FIG. 5.



From photomicrograph of suboxide precipitate from two cubic centimetres of 3 per 1000 solution of dextrose, two cubic centimetres of Fehling's solution, and two milligrammes of creatinine. Magnified 440 diameters.

By other agency than that of creatinine a corresponding result may be brought about. I will refer to the effect of albumin and ammonia, which has been already alluded to as supplying an illustration of an instructive nature. In the presence of albumin alone no deviation *from* the *ordinary* character of precipitate occurs. In the presence of ammonia the precipitate falls in a finer form, but nevertheless assumes a reddish character. In the conjoint presence of albumin and ammonia, however, it comes down in the yellow state and in character agrees with the condition presented as a result of the action of creatinine. Reference to Figs. 4 and 5, giving photomicrographic representations of the two precipitates, shows the close accord in microscopic appearance that exists between them.

Inhibition of suboxide precipitation, which constitutes the second point that was mentioned as presenting itself for consideration, is a phenomenon that calls for broad consideration from the fact, as will be seen when the discussion of its source of production is reached, that we have a complicated set of occurrences to give attention to. Let us here, in the first place, see what is actually observed when small quantities of sugar are boiled with Fehling's solution in the presence of creatinine.

If two cubic centimetres of Fehling's solution are boiled with two cubic centimetres of a 3 per 1000 solution of dextrose and two milligrammes of creatinine, which stand as representative of the *ordinary* amount of creatinine present in two cubic centimetres of urine, it is noticed that a suboxide precipitate falls almost, or quite, as *quickly* as in the absence of creatinine. It is true the two precipitates are different in character, but this is a point bearing *on the* other side of the question and therefore *one not now being* considered. If, next, instead of two *milligrammes* of creatinine, ten milligrammes be *employed*, *precipitation is* found to be perceptibly delayed, and a *decided* fading of blue (reduction without precipitation) *is perceived* to occur before the precipitate appears.

Presidential Address

ON

SCIENCE IN ITS APPLICATION TO NATIONAL HEALTH.

Delivered at the Seventy-fifth Annual Meeting of the British Medical Association on Tuesday, July 30th, 1907,

BY HENRY DAVY, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN, ROYAL DEVON AND EXETER HOSPITAL.

[AT the commencement of his address Dr. Davy welcomed the Association to the ancient city of Exeter, a city whose first charter dates from Henry II. Passing on to the medical history of Exeter he mentioned the founding of the hospital in 1741 by Alured Clarke, the then dean. Among prominent members of the hospital staff he referred to John Blackall, and Thomas Shapter, physicians; and John Sheldon, Samuel Barnes, John Harris, and John Haddy James, surgeons, the last-named having been President of the Association when under the title of the Provincial Medical and Surgical Association it met in Exeter 65 years ago. Continuing, Dr. Davy reminded his audience of the enormous changes which had occurred in these 65 years. The chief change was due to the growth of knowledge founded upon systematic experiment—i.e., "scientific" knowledge, and it is this knowledge which distinguishes the medicine of the day from the medicine of the early "forties." Dr. Davy went on to refer to the Darwinian theory and showed its influence upon medicine, for, as Darwin stated, "the only way to keep any organ or structure in health is by proper and adequate use thereof." He continued :—]

As I have before stated, Darwin shows "that the only way to keep any organ or structure in health is by proper and adequate use thereof," and I think that the value of this axiom has not been sufficiently recognised in considering the question of physical deterioration and its remedy, especially as it affects the muscular system; for many changes have taken place since 1842 in the environment of the individual and of the nation, all tending to reduce the muscular work done by the people, and in advance of everything else which has effected this result I would place the extended use of machinery. In every department of work, in every trade and business, each succeeding year finds us depending more and more on "labour-saving machines," every new machine tending more and more to replace muscular work, until at last in some manufactures the operative has little or no work for his muscles to do except just attending to the machine driven by steam or electricity by which all the work that used to be the result of his muscular activity is now accomplished. But, in addition to the development of machinery, many other causes have contributed to the same end. The nation has become much more urban than it used to be. Villages and country towns, with all their facilities for healthy muscular work in the open air, have diminished; big centres of trade and manufactures have increased in population. Railroads have extended networks of lines in every direction, so that travelling is made easy without any exertion, and the inhabitants of our towns have, in addition, tramways and omnibuses to take them from their houses to their work without the necessity of even the exercise of a long walk. Then, too, our habits have changed. We have perhaps as great a love of games as ever, but much of the muscular work has been taken from them. Your rich man sits or stands whilst his grouse or his pheasants are driven towards him, instead of walking the moors or woods to find them; the poorer man pays his entrance money to see a few experts playing cricket or football instead of exercising his muscles by playing the game himself; whilst some of the most manly and best exercises, such as wrestling, boxing, and fencing, have almost become extinct throughout the country. As Henry Drummond so well puts it, "Vigour of limb is not to be found in common life, we look for it in the gymnasium; agility is relegated to the hippodrome; once all men were athletes, now you have to pay to see them."

Now this subject, relating to deficient use of the muscles, opens out a very wide question, affecting as it does the work of every other organ of the body, and it is needful that our profession should recognise its importance. For a large part of the metabolism of food takes place in the muscular system, so that the amount of food required by the body, the amount of animal heat to be produced and to be got rid of, the amount of excretory products to be eliminated by the excretory organs, should all depend upon the amount of muscular work done; and much disease would be prevented, and in many cases much better health enjoyed, if this fact were more thoroughly understood and acted upon. It is somewhat of a reflection on our profession that we often treat our patients with drugs when all that they require is more exercise or less food. Also, that we are leaving it to various professors of Swedish exercises to teach us how much can be done to restore health, and to keep people in good health, by properly regulated muscular work. History repeats itself; the first physicians appointed by the authorities of the ancient Greek towns were trained gymnasts from more or less celebrated gymnasia, who treated their patients with regulated diet and regular exercise; and if the English in the twentieth century are to keep themselves free from physical deterioration, our profession must put themselves in the van of a similar movement and show how necessary physical culture and muscular activity are to a nation of "muscular degenerates." It should not be left to professors of Swedish exercises to lecture on physical culture, to advertise its sovereign virtues, and to direct the kind of exercise to be used. I will go further, and say that if it is left entirely in non-professional hands much harm will eventually result; for no treatment requires more care and supervision than Swedish exercises when used by anæmic patients or those with weak conditions of the heart; and although I believe that these exercises are of the very greatest value to healthy men, and can with great advantage be used by all who are compelled to lead a sedentary life, yet in a condition of ill-health they ought only to be used under the careful supervision of a qualified and experienced medical man.

Physical culture is, in my opinion, one of the most pressing questions of the day, for it is by it alone that we have a proper remedy for the state of muscular degeneration which is so prevalent. It ought to be considered by every educational authority, for by its use dwellers in city and country alike can have their muscular systems built up and developed to a healthy standard. There is no need that any collection of children who are not diseased should become a class of muscular degenerates. It is a very serious matter, when you come to think of it, that a considerable number of healthy, well-fed boys from some of our best public schools are too physically undeveloped to join the army as officers until they have undergone a course of physical culture after leaving school, and that large numbers of children in the elementary schools are diseased and physically undeveloped. For the children of to-day are the men and women who compose the nation of to-morrow, and if they are diseased and physically deteriorated the nation in the near future will be equally affected.

Is it sufficiently recognised how greatly the future of the nation is decided during the school life of its children? It is while the children are at school that you must give them the foundations on which the whole of their future—physical, intellectual, and moral—is to be reared, and if they are not shown how to develop their bodies and keep them in health, the only chance of their learning it has been missed. It is also essential to see that during their school life they are not exposed to contamination from disease, and this can only be done by placing them under the supervision of a trained and qualified medical man, as is done in Japan and in nearly every other country in Europe except England. As the Committee on Physical Deterioration emphatically recommends, every school in the country without exception should be under the supervision of a properly trained medical officer. It should be his duty, with his assistants, to examine every pupil, to see who are healthy and who are diseased, who are fit for a course of physical culture and who are not, and generally to look after the health and development of the children. How necessary such medical supervision must be is proved by the fact that Dr. Alfred Greenwood, medical officer of health of Blackburn, in an examination of 388 school children of that town, found that no less than 54 children were affected with some form of tuberculosis, and of this number 34 had tuberculosis of one or both lungs.

I would recommend to the notice of all educational authorities the example of Rugby School and of the scheme originated there by Dr. C. Dukes, one of the best-recognised work of Maschke[3] who says that creatinine *combines* with cuprous oxide, forming a compound which separates out of a hot solution on cooling as a white flocculent precipitate *suspended in a colourless mother-liquid.* This statement, it will be seen, stands in accord with what I myself observed and does not fit in consistently with Enry's explanation of the mechanism of the anomalous reaction obtainable in connexion with Fehling's test and urine.

In his second paper in the *Biochemical Journal*[4] Dr. MacLean adduces experimental work directed towards showing that the amount of ammonia capable of being evolved from creatinine is inadequate to account for the suboxide of copper being held in solution in connexion with the anomalous reaction obtained on testing urine *containing slightly beyond* the ordinary amount of sugar with Fehling's solution. At p. 158 he gives a table representing the effect of adding an increasing number of drops of an aqueous solution of ammonia consisting of 1 part of strong ammonia (0·880) in 10. It is stated that up *to four drops no deviation* is produced from the ordinary reaction observed on boiling one cubic centimetre of a 1 per 1000 dextrose solution with one cubic centimetre of Fehling's solution, and that with six drops the reaction is only delayed a few seconds. It may be said that with the ordinary *mode of applying the test* it is difficult, if not impossible, from the condensed granular form assumed by the precipitate to determine the exact moment at which the first sign of reaction presents itself where no ammonia is added, on account of the obscuring effect of the surplus *blue-coloured, unreduced liquid* existing. By heating over a flame also it must be considered impossible to get the equality with respect to temperature that is requisite for enabling a trustworthy conclusion to be drawn.

The difficulties here presented are to be met by employing a test solution with the copper element in it adjusted to the reducing power of the sugar solution and, for the application of heat, by immersion of the tubes in a boiling saturated solution of chloride of sodium, in which position they are in a state of equality and, placed side by side, are so circumstanced as to permit of the result being read off with precision. The cupric oxide in one cubic centimetre of Fehling's solution is reduced by five milligrammes of sugar. Ordinary Fehling's solution stands, therefore, as the corresponding equivalent of a 5 per 1000 solution of dextrose. To adjust the test to a 1 per *1000 solution* all that is requisite is to dilute the copper half of it to the extent of 1 in 5. This gives a liquid which is brought to a colourless state on boiling with an equal volume of a 1 per 1000 solution of sugar. There is no change in the constitution of the test in any other respect than in the amount *of its* copper constituent. The adjustment to any other strength of sugar solution can be similarly made. For instance, for a 3 per 1000 solution three volumes of the copper half of the test should be diluted with two volumes of water.

Adopting the method of procedure that has been described, we are placed in a position to see with facility and exactitude the true nature of the result produced, and viewed in this way the table given by Dr. MacLean does not supply a correct representation. It is not correct *to represent no effect as* being producible by one to four drops of the dilute solution of ammonia. In reality, comparing the application of the test without the ammonia solution and with one drop of it, precipitation is noticed to occur in the former case just appreciably in advance of the other, and in proof of an effect being exerted it is observable that the precipitate is of a distinctly less red colour. After two drops there is a distinctly measurable interval which in the instance timed with the chronograph amounted to four seconds. *After four* drops the *interval amounted to seven* seconds. In the table given by Dr. MacLean it is made to appear that in all these instances precipitation occurs at the same time. After six drops of the ammonia solution the interval was observed to stand at *12 seconds ; after eight drops*, 15; after 12 drops, 20; after 16 drops, 38; and here complete decolouration, meaning complete reduction, took place before precipitation occurred.

Accompanying the delay of precipitation *by the influence* of ammonia the *colour of the precipitate* becomes progressively altered, passing more and more to pale yellow as the quantity of the agent is augmented. Hence, this affords a measure of effect produced and corroborates *the other* testimony in showing that the action of ammonia has been much under-rated.

Following the table referring to ammonia a table is given by Dr. MacLean showing the effect of boiling one up to four milligrammes of creatinine with one cubic centimetre of a 1 per 1000 dextrose solution and one cubic centimetre of Fehling's solution, and this *is succeeded by* experimental evidence pointing to inadequacy of the ammonia capable of being evolved from the creatinine to produce the inhibitory action that is being considered. Then it is remarked (p. 159) that "urea in the percentage in which it occurs in urine yields much more ammonia than the kreatinin of an equal amount of urine, and yet it possesses no apparent *retarding effects*; for a very dilute solution of dextrose (less than 0·01 per cent.) introduced into a 2·3 per cent. urea solution and mixed with equal parts of Fehling's solution gives quite a distinct reaction."

It is to be conceded that the amount of ammonia derivable from small quantities of creatinine is not sufficient alone to produce the inhibiting effect that occurs, but it is open to demonstration that when creatinine is associated with the ammonia generating *product—urea, an effect is producible* beyond that which is capable of being occasioned by creatinine alone.

Adopting the mode of experimenting that I have previously described *it is in the first place susceptible of* being shown that urea alone *possesses a certain amount of* inhibiting influence. On heating in the boiling saline solution one cubic centimetre of a 1 per 1000 solution of sugar and one cubic centimetre of adjusted Fehling's solution by the side of a *similar admixture* containing *in addition two* drops of a 40 per cent. solution of urea, one drop of which gives to the one cubic centimetre of the sugar solution a proportion of urea equivalent to that existing in normal urine, it is seen that the reaction in the two tubes *starts practically simultaneously.* With the addition of four drops of the urea solution, however, the reaction occurs decidedly in arrear of the other and with eight drops an interval of from 20 to 25 seconds has been timed between them.

Associated with a minimum quantity of creatinine a small quantity of urea greatly enhances its effect. If two tubes are taken, one containing one cubic centimetre of a 1 per 1000 dextrose solution and one cubic centimetre of adjusted Fehling's solution with 0·5 *milligramme of creatinine* and the other a corresponding *admixture* with the addition of two drops of the urea solution, the reaction in the case of the latter has been noticed to be inhibited for a period of 35 seconds. Urea, then, from which ammonia is generated on being boiled with *Fehling's solution, can be demonstrated to add to* the effect of creatinine in inhibiting the reaction produced by sugar. A minimum quantity of creatinine was purposely taken so that the result might not be obscured by the action of the urea being overpowered. Through the experiment *the existence of the* underlying operative capacity is brought into view.

The action of creatinine in the direction of interfering with coalescence is an exceedingly powerful one, so much so that quite a small amount of it is sufficient to influence a very large amount of suboxide. There may be no delay of precipitation observable, but the colour and microscopic appearance of the precipitate show that coalescence has been interfered with. By observation, for instance, it is to be *seen that one-twentieth of* a milligramme of creatinine added to one cubic centimetre of a 5 per 1000 solution of dextrose is capable of altering the character of the precipitate produced on boiling with one cubic *centimetre* of *Fehling's solution. No effect* in delaying precipitation is to be perceived but a precipitate of a more yellow colour than normal falls, and it is seen on microscopic examination to consist of finer particles. Thus, upon the *strength of* these premisses it has *to* be stated that one milligramme of *creatinine* has the power of modifying the character of about 200 milligrammes of suboxide precipitate.

It cannot fail to have been recognised that *in connexion* with the anomalous reaction we have a complicated set of phenomena *to* deal with and what I have now to mention adds to the complication existing. Out of keeping with what might be expected, it is found that ammonia *in small* amount reverses or *inhibits* the action of creatinine. To show *this* it *is* convenient to work with one milligramme of creatinine and a 1 in 10 *solution* of ammonia. Adopting this plan the *following* are the results that were obtained in a set of observations that I will *refer to.* With one cubic centimetre of a 1 left to voluntary associations which must of necessity be unable satisfactorily to deal with a task of such magnitude. Are we to admit that tuberculosis alone amongst the infectious diseases is to have no precautions insisted on with regard to disinfection? Are we forever to allow consumptives to disseminate their infectious sputum in the streets of our towns? or are we to allow them alone of infectious patients to stay in any hotel or lodging in England without taking any precautions? Every nation in Europe, except England, has awakened to the need of dealing with this disease on scientific lines, and it is time that we followed their example. I am quite aware of the difficulties which surround the whole question, and I do not wish to put forward my own views as to the measures which are practicable in dealing with the disease. All one-sided statements only tend to obscure the issues and increase the difficulties of the situation. Satisfactory legislation can only be obtained by its careful consideration from many points of view; but is it not the time for the Government to make a careful inquiry into the subject, and that, having obtained the best expert and other opinion available, and having considered the precautions which other countries are taking, it should bring forward legislation to deal with this disease, which yearly destroys nearly 60,000 of our people and brings misfortune and sorrow into some 600,000 homes in our country. For, gentlemen, it is only by careful inquiry and by carefully applying the science of the day, as far as is practicable, that we can hope to do away with a large mass of disease which we already know to be preventable, and it is in this direction that our Association can do much useful service. It is here at these our annual meetings and in the pages of our weekly journal that so much of the truth is arrived at about disease, its causes, and its modes of treatment. It is here that we examine the theories and opinions of individuals, and filter, as it were, the unproved residuum from the truth which is to be of use to the world. But it must remain, after all, with the Government to apply this truth to the legislation of the country and to the everyday life of the people. That it is possible for a Government to do this has been proved by the Government of Japan. You have here a nation which had its own civilisation, and whose people were well educated in Chinese classics and literature, but who were not acquainted with the science which is the distinguishing feature of Western civilisation. For 250 years this people enjoyed peace, and during this time had been able carefully to examine the work being done by other nations. They saw the value of science and scientific developments of the Western world, all of it new to their modes of thought and life; they determined to bring it into their mode of life, and they have done this in a thoroughly systematic manner.

[3] Zeitschrift für Analytische Chemie, Band xvii., 1878, p. 134.

[4] Loc. cit.

Earlier in this address I quoted to you the systematic manner in which they introduced physical exercises, gymnastics, and games into all their schools, and we can see the value of their system yet further shown in the marvellous freedom from disease which was apparent in their armies during the late Russo-Japanese war. Through the kindness of Admiral White I have been able to make a study of the book of rules which each Japanese officer took into that campaign. They were drawn up by a body of experts, military surgeons, and they deal with almost every contingency likely to be met with in warfare. There has never before in history been so systematic an application of the science of the day to the everyday life of a soldier, nor are there many armies in the world sufficiently educated in hygiene to understand such minute details. But all the children in Japan are taught in their schools the principles of elementary hygiene, and, carrying out the directions given to them, the soldiers marched to victory with less illness from preventable disease than ever occurred in any previous campaign; and they thus gave a demonstration to all nations of the importance of the application of the science of the day in the prevention of disease. If Japan can thus bring science to assist in preserving the health and physique of their nation, England can do the same, or else she must eventually take a back seat in that concourse of nations in which only the fittest will be supreme. In one of his most striking passages Rudyard Kipling says: "We are a great people and very strong, but we build our empire in a very wasteful way—on the bones of the dead who have died from disease!" It is for our profession, gentlemen, as the advisers of the nation on all matters of health, to show how much of this terrible waste can be prevented; and just in proportion as we succeed in doing this, in that proportion shall we be carrying out the highest purpose of our profession in maintaining the health of the individual and in preventing the degeneration of the nation.

Address in Medicine

ENTITLED

A PLEA FOR ACCURACY OF THOUGHT IN MEDICINE.

Delivered at the Seventy-fifth Annual Meeting of the British Medical Association on Wednesday, July 31st, 1907,

BY W. HALE WHITE, M.D. LOND.,
SENIOR PHYSICIAN, GUY'S HOSPITAL.

[Dr. Hale White, after thanking the Association for the honour done to him in requesting him to give the Address in Medicine, begged his hearers to impress upon the members of the public the debt which they owe to medicine and how the public ought to help to endow professorships for medical research and teaching. Passing to the main subject of his address he said that "sometimes we retard the progress of our science by being afraid to say that we do not know. We are prone to find some explanation and to be content with a false explanation." As an example of this he referred to the subject of gout. All that we really know about gout is that urate of sodium is deposited in some of the tissues and that the blood contains an excess of uric acid. The cause of many cases of neuralgia, sciatica, and bronchitis is set down to gout, but where are the figures from the post-mortem room showing that sufferers from these diseases have deposits of sodium urate or an excess of uric acid in the blood? Others, not thinking that these conditions can be called gouty on such slender evidence, say, "Let us imagine that the gout is irregular . ... or suppressed and then we can ascribe them to it." Others link to this hypothesis the theory that the symptoms of irregular gout are due to excess of uric acid, and, continued Dr. Hale White:—]

Some do this without knowing the amount of uric acid present in the blood of a healthy person, without drawing any distinctions between endogenous and exogenous uric acid, without any attempt to estimate the uric acid in the patient's blood, without any experimental evidence that the injection of uric acid into the blood produces the symptoms in question, and without any thought of the fact that in some forms of leukæmia there is an excess of uric acid in the blood without the symptoms supposed to indicate suppressed gout. This doctrine has become so widespread that even the public tell us that their symptoms are caused by an excess of acid. Having assumed, not proved, that the symptoms the patient has are due to irregular gout and having assumed, not proved, that this is due to an excess of uric acid, the next assumption made is that certain foods cause an excess of uric acid; some say carbohydrates, some say fats, some say proteids, and it would be quite easy for a patient to consult three medical men in turn and if he followed all his diet would be water and nothing else. He who believes proteids harmful is the most artistic, for he has an eye to colour and may, as a concession, allow white meat, although he prohibits red. Where on earth is the justification for this? Are there any experiments showing that steaks lead to more uric acid in the blood than chicken? Have a hundred cases of so-called irregular gout been published and contrasted with another hundred similar in their treatment except that in one series red meat was replaced by an equal amount of white? Surely you will agree with me that all this is not a credit to us as members of a scientific profession. The simple fact that although gout has become much less common the consumption of meat has enormously increased ought alone to make those who forbid proteids pause. The imagination of some has carried them still further. The fact that both gout and chronic osteo arthritis are long-standing diseases of joints has led them to think that as sufferers from one should be dieted, so those afflicted with the other, hence we find patients who have chronic osteo-arthritis forbidden various articles of food—sometimes, for example, sugar. Looked at calmly this is extraordinary, for there is not an atom of evidence that any particular fluid which had been obtained from an uncorked tin. I saw the child about half an hour after the occurrence who was then suffering from the usual effects of carbolic acid poisoning about the mouth and fauces. The breathing was accompanied by a rattling sound in the larynx and the patient was in evident distress. I administered five drops of tincture of iodine in a teaspoonful of water, which when swallowed gave immediate relief. Shortly afterwards I repeated the dose and gave instructions before leaving for two more doses to be given at intervals of four hours. On the next day the patient appeared to be in a normal condition except that the voice was still slightly hoarse. In this case probably very little of the Jeyes' fluid had reached the stomach.

CASE 3.—The patient, a child, aged two years, had swallowed some Jeyes' fluid from a bottle which he had found on the floor and he was discovered by his parents almost immediately afterwards. The nearest medical practitioner was called in and he attended to the patient for the first 30 hours but as the parents were old patients of mine he kindly, at their special request, handed the case over to me, as they were unable to pay consultation fees. The condition of the patient when I first saw him on May 20th, 1907, was as follows. He was lying in bed extremely ill. The respirations were 80 and were accompanied by a rattling sound in the larynx. He was unable to make a sound above a whisper. The tongue and fauces were bleached, the pulse was 140, and the temperature was 104° F. The abdomen was generally distended and tympanitic. The bowels had been opened twice during the last six hours, the motions being very dark in colour and loose. Urine could not be obtained. The treatment had been the administration of egg albumin, followed by oil and an alkaline mixture. I ordered five minim doses of tincture of iodine in a teaspoonful of water to be given every four hours, and administered the first dose myself. On the 21st the patient had passed a fairly good night and he looked easier. The temperature was 101·6°, the pulse was 140, and the respirations were 75. The abdomen was less distended and did not appear painful on pressure. The bowels had been opened twice, the first motion being rather dark and loose, with some mucus, while the second motion had been normal in colour, semi-solid, and free from mucus. The iodine solution was continued every six hours, and a mixture containing four minims of tincture of digitalis, ten minims of spirit of chloroform, 16 minims of syrup of orange peel, with water to one drachm was given every four hours as a heart and lung tonic. On the 22nd the child was much better. The temperature was 99°, the pulse was 85, and the respirations were 40. The bowels were not opened on this day. The patient had slept well and had taken liquid nourishment, mostly milk, freely. The abdomen was soft but was still slightly distended. The child took one more dose of tincture of iodine and refused all further medicine, except one grain of calomel. On the 23rd the patient was sleeping comfortably when I called and appeared to be in a normal state. The bowels had been open once normally and as fees were a consideration the mother told me that she would let me know if any untoward symptoms occurred. I looked in a week later and found the child running about in his usual health, with the exception that the throat was slightly sore and the voice was somewhat hoarse.

The first two cases recorded above demonstrate the value of iodine for the ill-effects of carbolic acid on the mouth and throat, when administered soon after the poison has been swallowed and before any symptoms which can be distinctly traced to its effects on the stomach and intestines have had time to develop. The third case is very interesting, as in this we have all the general toxic effects of the poison fully developed, as well as distinct signs, in the tympanitic abdomen and the dark and slimy stools, of the poison having reached the stomach and intestines and set up changes there. The administration of iodine can, I think, in this case be safely credited with the happy result obtained, and I submit that I am justified in recording it in that light. Further records are, however, very desirable and it is to be hoped that in future they will be forthcoming.

The chemical reaction between iodine and carbolic acid is very easily demonstrated. If a solution of carbolic acid be added gradually to a solution of iodine in a test tube and a gentle heat be applied, the latter solution at a certain point becomes completely decolourised, and if tested by means of a starch solution for iodine it will no longer give the blue colour reaction, showing that the iodine has gone into actual chemical combination with the phenol—a phenol iodide is evidently formed. The effect on the skin or tongue can be easily tested by placing a little strong solution of carbolic acid on either, and as soon as the typical effects are experienced neutralising it with a solution of iodine. The effect will be almost immediate as regards sensation.

The neutralising power of iodine compared with that of the alkaline sulphates on the skin or mucous membrane may be tested in the same way. The results of the application of iodine will be found to be much more effectual and permanent than those of the alkaline sulphates.

The chemical compound formed as a result of the reaction between iodine and phenol is apparently harmless, if one may judge by the experience of its effects in the three cases recorded, and it should consequently have an advantage over that formed by the reaction between phenol and the alkaline sulphates—viz., the sulpho carbolates—seeing that the latter salts are not entirely free from deleterious results. The fact that the iodine in tincture of iodine is mostly in a free state gives it a great advantage over other bodies which have to undergo more complicated changes in their chemical reaction with phenol.

The pharmacopœial doses of tincture of iodine are given at from two to five minims, but other works place them at from five to 20 minims; it would, however, be necessary to increase the dose considerably when using it as an antidote in carbolic acid poisoning, varying it according to the amount of poison that had been absorbed, possibly up to drachm doses and more in severe cases. In test-tube reactions one minim of liquid carbolic acid, B.P., neutralises about one minim of tincture of iodine, with the application of gentle heat, but continued heating will cause a still further quantity of iodine to become decolourised; apparently at the higher temperature a larger amount of iodine goes into combination with the phenol. The question as to what is the exact proportion of iodine necessary to neutralise a given amount of phenol in the body is a difficult one to answer, but probably for practical purposes we may take it that equal quantities of tincture of iodine and phenol are complemental.

Darenth road, N.

NOTES OF A CASE OF ADDISON'S DISEASE IN A NEGRESS.

BY R. SEHEULT, M.D., C.M. EDIN.,
RESIDENT SURGEON, SAN FERNANDO HOSPITAL, TRINIDAD

THE rarity of Addison's disease, especially in the dark-skinned races, has induced me to publish the notes of the following case.

The patient, a negress, aged 65 years, was admitted to the San Fernando Hospital on March 19th, 1906, with a history of progressive debility, occasional attacks of vomiting and diarrhœa, and intense black pigmentation of the hands and face for six months. Two of the hospital nurses who had known her for years were attracted by the change in the colour of her face and hands and were able to confirm her statement with regard to the abnormal pigmentation complained of. On admission she was found to be fairly nourished, slightly anæmic, and in a state of great prostration. Owing to extreme weakness she was compelled to remain in the recumbent position in bed. She complained of pain in the small of the back and in the abdomen. The face and backs of the hands and fingers were intensely black—much blacker in hue than other parts of the body. The palms of the hands were also abnormally pigmented but to a lesser degree than the face. There were numerous irregularly defined areas of pigmentation on the mucous membrane of the cheek, gums, and tongue. Her pulse was frequent, small, and regular. Examination of the heart and lungs disclosed nothing abnormal except an occasional systolic murmur at the apex which was hæmic in character. The urine contained a trace of albumin. Nothing of note was detected on examination of the abdomen. Her temperature was normal. On the following day she became collapsed, passed into a semi-comatose condition, and died somewhat suddenly.

At the necropsy the heart was flabby; it showed no sign of endocarditis. The lungs were apparently healthy. The liver and spleen presented nothing abnormal to the naked eye but their capsules were much thickened and adherent to the parietal peritoneum. The capsules of the and energy have been thrown away upon other medical statistics besides those connected with inheritance. Sometimes the very words are used wrongly. I often read at the end of an insurance report a prophecy that the proposer will live to the average age; *but this is almost certain*, that whatever his age at death may be it will not be the average age. It must be left to expert statisticians to reform technical errors, but it is easy to indicate a few that are obvious. Frequently the mistake is made of dealing with far too few figures; often the very data are wrong, as I have just shown in connexion with hæmatemesis; allowance is rarely made for the number of persons alive at different ages; it is very common to see figures published believed to prove the effect of this or that treatment without any allusion to the rapidity of recovery if no treatment had been adopted, and often the figures do not tell us what we desire to know. For example, statistics are published showing the frequency of recovery after some difficult operation. In the first place, for these to be of any practical use we want to be able to contrast them with figures showing the mortality among those not submitted to operation. Next, we ought to compare the expectancy of life among those who are not operated upon with that of those who submit to operation, for it is clear that if the operation considerably shortens the life of many the total harm done by the operation may be more than the total good. Then, again, although it is interesting to know the degree of perfection to which any particular surgeon can carry the difficult art of operating, and so lower the mortality, yet, as all the patients cannot possibly go to the one skilful man, it is far more important to know the usual mortality among operating surgeons. These are only some of the points we have to consider; but let us take as an illustration the operation for a gall-stone impacted in the common duct. When trying to estimate the propriety of this we must bear in mind that when impacted in the common duct a gall-stone rarely causes death. From the years 1854 to 1894 only one patient not operated upon died in Guy's Hospital from an impacted gall-stone, the total number of deaths from all causes having been over 20,000. Naunyn has only once known the condition fatal. Some distinguished surgeons have operated upon several cases with complete success, but, on the other hand, Mr. J. Bland-Sutton, doing the right thing, and taking the figures not only of an individual surgeon, but from the chief London hospitals, and the Leeds and Newcastle infirmaries, finds that out of 35 cases operated upon ten died, or nearly 30 per cent. But it might be urged that, bearing in mind the risk of fatal cholangitis and the tediousness and discomfort of passing an impacted gall-stone naturally, it is worth while to submit to operation, but before coming to this conclusion we must proceed very carefully, considering the high mortality following operation. Further, it is notoriously difficult to distinguish between an impacted gall-stone and malignant disease, so that in estimating the benefit that follows operation we must take into account the shortening of life owing to operation among those who are operated upon in the belief that they have a gall-stone, although they really have malignant disease. Again, figures have been published showing that after excision of a cancer from the stomach a few patients were alive at the end of four or five years, and it is assumed that their life has been prolonged; this may be so, but we ought, before concluding that it is wise to excise cancers from the stomach, to know how many people have had their life shortened and, as nearly as possible, how much it has been shortened by the operation. To take another example. A variety of operations have been performed for the relief of those who suffer from exophthalmic goitre, but before we can decide whether this should be done we ought to know the subsequent health and duration of life of all those operated upon and contrast it with the subsequent health and expectancy of an equal number of patients who, having the disease equally severely, have not submitted to operation. Please let it be understood that I am not in any old-fashioned way objecting to the advances of surgery. Far from it, the debt that physicians owe to modern surgery is very great; every year hundreds of people whom we physicians are powerless to help have their health restored to them by surgeons and my surgical friends know well that not a week goes by but that I seek their aid. Nor am I here attempting to decide whether gall-stones should be excised from the common duct, or cancer from the stomach, or whether operations should be performed for exophthalmic goitre. The sole reason why I have taken examples of operations upon medical cases to illustrate the care which must be exercised before arriving at a conclusion derived from figures is that it is easier to see the result of a surgical operation than that of other modes of treatment, but I can readily take an instance from medicine—namely, the treatment of typhoid fever by bathing. Many large collections of cases have been published, showing that if all the patients whose temperature exceeds a certain point are bathed the mortality is lowered, and from that fact it is argued that all patients whose temperature exceeds that point should be bathed. But this does not follow, for, supposing the bathing killed some who would otherwise not have died, but saved more who would have died if they had not been bathed, the mortality would be lowered, although the treatment would have killed some. Surely the right thing to do is not to bathe all, but to select to the best of our judgment those who should be bathed.

But when we have got our figures the problem is often much more obscure than any of those just quoted and demands a special training in the use of statistics that few medical men possess. A good illustration of the extreme difficulty of dealing with medical statistical problems is the question whether tuberculous disease is hereditary or, as we should now say, whether the children of tuberculous parents inherit any special liability to infection by the tubercle bacillus. Many papers have been written on this subject, but hardly any are free from fallacy; some are so full of errors that they are quite valueless. Often the evidence is fallacious, as, for example, when the writer forgets that all experience gained in the post-mortem room shows that many have tuberculous disease who, so far as we know, gave no evidence of it during their life. Even figures from life insurance societies dealt with by actuaries are not free from fallacies of evidence, for they can take no account of those who are born of tuberculous parents and die from tuberculous disease before they come up for examination for life insurance. Often the reasoning is fallacious also, as, for instance, it is stated that such and such a proportion of sufferers from pulmonary tuberculosis have consumptive parents, forgetful of the fact that this is worth little unless we know what proportion of people who have not got pulmonary tuberculosis have consumptive parents; and, beyond obvious pitfalls such as these, there are others that only expert statisticians can avoid. A few years ago when it was discovered that there could be no pulmonary tuberculosis without infection by tubercle bacilli many of the medical profession, without any careful consideration, threw overboard the belief that inheritance played any part, and it was maintained that the children of tuberculous parents were not more liable than others to pulmonary tuberculosis; but Professor Karl Pearson has recently published a paper in which he states that the inheritance of a special liability to infection by tubercle bacilli plays a very important part. Much has been made of cases in which it appeared that pulmonary tuberculosis has been transmitted from husband to wife, or *vice versâ*; but, as a rule, no attempt is made to calculate the probability that both might have such a common disease quite apart from infection from one to the other, and therefore it is interesting to read that Professor Karl Pearson says: "There is clearly no need in such cases to appeal to infection from husband or wife to account for the small number of cases in which both parents suffered." I am afraid that frequently we describe conditions as having a special association without any endeavour to determine whether they are more frequently associated than might be expected as a matter of chance. The statistics about insanity and cancer also show the extreme difficulty of a proper use of medical figures. I have often urged what I am glad to see he urges, that to deal with figures requires a special training which is enjoyed by but few of us; we should not draw conclusions from statistics unless we obtain the help of those specially educated to their use. But statistics are only part of a larger matter—namely, the extraordinary width of knowledge required for our science of medicine. Properly to appreciate the differences between the vitalists and their opponents a training in metaphysics is desirable. A medical man ought to know his physiology and pathology well, but much of these is founded on chemistry and physics; indeed, physiological chemistry is already a department of physiology, and bacteriology and protozoology are linked to pathology. It is, in truth, quite impossible for a medical man to keep abreast excellent feature is that in connexion with each condition discussed there is also added a paragraph outlining what usually happens in that condition if operative treatment is not carried out.

The work is obviously based upon a large experience and, where possible, statistics are given of the results of various forms of treatment recommended. On the whole, however, we must confess to being somewhat disappointed with the general plan of the book and the indications given. In each chapter some remarks are included on the etiology, pathological anatomy, clinical course, diagnosis, and differential diagnosis of the condition under consideration. These, Professor Schlesinger informs us, are included on the advice of colleagues whom he has consulted and are admittedly subordinate to the main purpose which he has in view—viz., to assist in arriving at a decision as to the advisability of operation in regard to a given case of a particular condition. To us they appear to serve little, if any, useful purpose. They are of necessity brief, incomplete, and often tedious from their very baldness. The object in view was in no sense to assist in the diagnosis of the condition but to arrive at a decision in regard to special forms of treatment. The space thus wasted might with advantage have been devoted to a more critical discussion of the specific indications for operative treatment, which are often stated in a few lines and in general terms. The conditions contra-indicating operation in regard to each disease are given in a separate paragraph and are usually explicit and should be useful.

The best sections of the book seem to be those devoted to diseases of the stomach and intestines, in which the results of recent work are incorporated and valuable information in regard to the choice of suitable cases of gastric ulcer and carcinoma for operative treatment is given. Useful appendices on Indications for the Induction of Premature Labour, on Operations on Diabetics, and on the General Influence of Operations on the Body, the last by Dr. Julius Schnitzler, are added at the end of the book. In the case of each disease or condition discussed a brief list of important papers dealing with the subject is appended, though the author explains, to avoid misconception, that these are given only with the object of assisting the reader to refer to special works and not as a complete bibliography. The translation gives the impression of being too literal; at any rate, the English is cast in a distinctly German mould.

Elements of Human Physiology. By E. H. STARLING, M.D. Lond., F.R.S., Jodrell Professor of Physiology, University College, London. Eighth edition. London: J. and A. Churchill. 1907. Pp. 716. Price 12s. 6d. net.

WHEN a text-book has reached its eighth edition there is little to be said either in the way of praise or criticism. The work under review is an admirable, compact, all-round exposition of the main facts and theories of physiology. Nearly 200 pages are devoted to what may be called general physiology, including a short account of the material basis of the body, the blood, and the contractile and conducting nerve structures. The author has adopted the term protein and the new term of E. Fischer, polypeptides, which includes such bodies as leucyl-tyrosine and its allies. In the matter of size and microscopic measurements we do not find such given in terms of μ but rather in parts of an inch—e.g., red human blood corpuscles as about $\frac{1}{3200}$ of an inch in diameter, the colourless $\frac{1}{2500}$ of an inch, and so on. These latter are spoken of as "probably" reproducing themselves by fission. Little is said about the blood platelets. Perhaps more should have been said on the estimation of hæmoglobin and the same might be said as to specific gravity (p. 84), and no indication of the size of fibrin fibres is given (p. 75). Nor is there any indication given of the size of muscle and nerve fibres, although there are diagrams of both without the magnifying power being given. In fact, in many of the histological diagrams the magnifying power is not stated. It would be convenient to do so in future editions. The "muscle press" is mentioned but it should be associated with the name of Kühne (p. 154). One of the most interesting facts about smooth muscle is its susceptibility to changes of temperature—as a rule, warming causes relaxation and cold a tonic contraction. It seems very doubtful whether any true rigor mortis occurs in smooth muscle. There is a short account of double innervation of smooth muscle as illustrated by the retracted penis.

The rest of the work deals with the special physiology of the various organs. In every case the subject matter is terse, concise, and to the point. We rather think that the hæmodromometer was invented by Volkmann and not by Volckmann (p. 203). The term antipeptone we hope will soon disappear, for it is not a definite compound but a mixture of bodies. The modern view as to the results of the energetic action of trypsin in pancreatic digestion working with the succus entericus is set forth; a thorough disintegration seems to be a necessary preliminary to the assimilation of any foreign form of proteid. No material changes have been made in the chapters on Digestion, Respiration, Excretion, and Metabolism. In the chapter on the Brain reference is made to the recent investigations of Campbell and Sherrington.

The work is a safe guide for the student and a good foundation on which to raise the superstructure obtainable from the study of more elaborate text-books.

The Licensed Trade: An Independent Survey. By EDWIN A. PRATT. London: John Murray. 1907. Pp. 329. Price 5s.

THERE is no social question which calls more for calm, dispassionate judgment than that of the drink problem and there are few subjects of discussion which seem to invite so much vituperation at the hands of extremists as does this one. Mr. Pratt started life with a sort of conviction that the teetotaler's views were correct. He had passively adopted, and had acted on, teetotal opinions since the days of his youth and had assumed that the aspersions of the teetotal faction in regard to the methods of the makers and dispensers of alcoholic drinks were true. He decided, however, to examine the question *de novo*, with the result that he found that his views were not entirely free from prejudice and were not in accordance with a full presentation of facts and he arrived at the conclusion that many of the statements advanced by the total abstainers were based "largely on exaggeration, misconceptions, and, indeed, conditions altogether incapable of attainment." His attitude, in short, became reversed in the light of the admirable principle, *Audi alteram partem.*

In this book he has, so to speak, compiled parallel columns and the net result of their inspection and consideration would appear to be a defence of "the trade" and its methods. With his definition of the word temperance as in reality a synonym for moderation few but mistaken zealots can quarrel, nor would any level-headed person discourage his desire to see all people temperate and sober, or dispute his view that freedom and justice are greater than even temperance and sobriety. When, however, we are told in regard to the administration of the liquor traffic that many of the attempted reforms of the licensing system might do far more harm than good we are at once on highly debateable ground. We are bound to recognise that with the human dispensation as it is the traffic in liquors is a *sine quâ non*, that alcoholic drinks would appear to supply a human need, but with all that we must admit that it is a dangerous traffic beset with multiple pitfalls for many and therefore a traffic which might be

Address in Surgery

ON

THE CONTAGION OF CANCER IN HUMAN BEINGS: AUTO-INOCULATION.

Delivered at the Seventy-fifth Annual Meeting of the British Medical Association on Thursday, August 1st, 1907,

BY HENRY TRENTHAM BUTLIN, F.R.C.S. ENG., D.C.L.,
CONSULTING SURGEON, ST. BARTHOLOMEW'S HOSPITAL.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—The question of the contagion of cancer in human beings has been often raised and as frequently decided—sometimes in favour of contagion, sometimes against it, according as the evidence is accepted or rejected. For there are two kinds of evidence—that which satisfies the inquirer who wishes to believe, and that which is required by the sceptic, just as there are two kinds of evidence regarding most theories and events. If the occurrence of cancer in a man and his wife who live in the same rooms be accepted as evidence of the contagion of cancer, whether the two were affected at the same time or years apart, whether the cancer of the one was of the same kind as the cancer of the other, whether the cancer was exposed or covered, then the case of contagion is not difficult to prove. And if the occurrence of cancer in the attendant on a cancer patient be accepted as evidence of the contagion of cancer, whether the cancer be of the same variety in both the patient and the attendant, whether it be internal or external, and whether it occur immediately in the attendant or only after the lapse of years, then surely there is ample evidence that cancer is contagious in the human subject. And of such a kind, for the most part, is the evidence which is adduced to prove the case.

But, if the philosophical mind is to be persuaded that cancer is contagious in human beings, it can never be by means of such flimsy evidence as this. Certain conditions must be laid down for the evidence, and those conditions must be adhered to with the strictest impartiality. I will presently state them. But, in order to do so with the greatest effect, it is first necessary to lay as it were a foundation for the discussion of the question, and even to define some of the terms which will be employed.

Let me say that when I speak of cancer as contagious I mean only that it is *communicable*, and I use the former term because it is more convenient and not so ponderous as the latter, but when I use it I do not do so with the intention of expressing a peculiar or special mode of communicability. Next, I would draw attention to certain conditions of cancer which are quite well known but which should be actively before the mind of him who investigates this subject. Thus two or more cancers may occur in the same individual. It is a matter of common observation that several *rodent ulcers* may attack the face, but no direct relation can be traced between them. In like manner the surface of the tongue may present two or more squamous carcinomata. Or an individual may suffer from squamous carcinoma of the larynx and from cylindrical carcinoma of the rectum. We speak of all these as cases of *multiple carcinoma*, and for the present we accept the theory that they have no direct relation to one another in the sense that no one of them depends for its occurrence on any other of them.

Next, carcinoma occurs in parts of the body which are in direct relation with one another through the medium of the lymph or blood. Thus, the breast is the seat of carcinoma and the axillary glands become affected. Or, carcinoma attacks the rectum and growths of carcinoma are discovered in the liver. In these cases the carcinoma of the glands or liver is of the same variety as the carcinoma of the breast or rectum and the theory is universally accepted that the one disease depends for its existence on the other, and that some part of the carcinoma, or something derived from the carcinoma, is conveyed from the breast into the glands through the medium of the lymph, or from the rectum into the liver through the medium of the blood. We call the carcinoma of the breast and rectum the primary disease and the carcinoma of the glands and liver the secondary disease; and we speak of this transference of the carcinoma as a *metastasis*, not a very good term perhaps—for it is defined to mean "the removal of the seat of a disease from one place to another"—but good enough, for every person who uses it in the pathology of malignant disease uses it in the same sense and each one knows what the other means by it.

Again, carcinoma is conveyed experimentally from one part of the same body to another or from one animal to another of the same species. A fragment or broken-up portion of the carcinoma is inserted, for the most part beneath the skin, where it takes root and grows and conducts itself with regard to its new surroundings precisely as the carcinoma from which it was derived does with regard to its surroundings. The fragment or portion thus planted is spoken of as a graft (*greffe*, *Impfung*) and the process is termed grafting, or inoculation, or transplantation, but the term *implantation* is more generally used in place of these terms, and I shall speak of this process throughout as implantation, that there may be no doubt of my meaning.

It is sometimes said that every successful implantation is neither more nor less than a metastasis and this, to a certain extent, is true but only within limits, for the conditions which surround the material which is implant growth, but it some important respects from those w lor third of the metastasis. Nevertheless, so frequent a was examined natural metastasis that it might reasonabl up epithelium and carcinoma would be most easily and rea sues." Had the one animal to another by introducing sor ted for a little matous material into the blood, which F as in the case convey it to various organs of the body, in ssity of micro- which it would be likely to find a suitable so naked eye ment for its maintenance and development. Exp than was however, taught us that this method is very unsucces it has almost ceased to be employed by those who e ment with cancer. Injection experiments might, perhap be more successful if they were practised in the lymph vessels; but this procedure is well-nigh impossible in the small animals with which experimenters have to do. We have further learned by experiment that the carcinoma which is successfully implanted invariably presents the characters of the carcinoma from which it was implanted, and that its metastases, like the metastases of the original carcinoma, are always of the same variety and that no transformation has yet been observed of one variety of carcinoma into another variety. It is conceivable that future experiments may yield a different result, but for the present we have no right to assume that the implantation of one variety of carcinoma can produce any other variety of carcinoma. We have learned that successful implantation is not easy, even in animals, and with tumours which have been most successfully dealt with, and that success depends largely on experience and practice and on the most minute observance of detail. We have learned that sepsis, whether of the implanted material or of the part in which the material is implanted, is an almost insuperable obstacle to success. We have learned that animals in which experimental implantation is most easy may be fed during long periods of time on food mixed with carcinoma without contracting the disease. And, finally, we have learned that healthy animals, which can be easily treated by implantation, do not contract the disease merely by being kept in the same dwellings (cages) with animals which are suffering from the disease.

This accumulation of knowledge of the last few years enables us to formulate, much more definitely than we could before, the conditions under which carcinoma is likely or unlikely to be accidentally communicated from one human being to another. Thus it will be at once apparent that all cases of reputed contagion of cancer in which the disease is not of the same variety must be unhesitatingly rejected; that cases must not be accepted where there is no evidence that the affected parts of the two individuals were from time to time in contact; that it is extremely improbable that contagion should take place from a covered cancer, such, for instance, as a cancer buried in the breast; or that the disease could be implanted in a part the covering of which has not been broken. These exclusions largely limit the number of possible cases of contagion and the limitation is still greater when it is taken into account that sepsis of the tumour or of the broken part which comes in contact with it is an almost absolute obstacle to the success of accidental implantation. For it is notorious that cancers which are exposed for the most part rapidly become septic and ulcerate as here—for we have nothing but praise for their presentment—while the price of the book could have been so far reduced as to make it more widely available, the perusal of its contents being at the same time a less formidable task upon which to embark. The translation is generally well done and the printing and get-up of the book are commendable.

LIBRARY TABLE.

Diseases of the Larynx. By HAROLD S. BARWELL, M.B. Lond., F.R.C.S. Eng.; Surgeon for Diseases of the Throat, St. George's Hospital; Laryngologist, Mount Vernon Hospital for Diseases of the Chest; Consulting Surgeon for Throat and Ear Diseases, Cripples' Home for Girls; Consulting Laryngologist, National Association for the Establishment and Maintenance of Sanatoria for Workers. With 21 figures. London: Henry Frowde and Hodder and Stoughton. Pp. 266. Price 5s. net.—This little book has been specially written to supply the need of a small work on the larynx and deals briefly and clearly with all the various pathological conditions met with in the larynx. It is very well illustrated and contains besides a very good selection of prescriptions. As will be expected from Mr. Barwell's previous work the chapter on laryngeal tuberculosis is particularly good. It is inevitable that in so small a book a small amount of space only should be devoted to each subject, but taking it altogether we think that Mr. Barwell is to be congratulated on the way in which he has accomplished his task and that without doubt this volume will prove of more use to the student and general practitioner than the majority of the more pretentious works dealing with the same subject.

The Refraction of the Eye: a Manual for Students. By GUSTAVUS HARTRIDGE, F.R.C.S. Eng., Senior Surgeon to the Royal Westminster Ophthalmic Hospital; Ophthalmic Surgeon to the Westminster Hospital, &c. With 109 illustrations. Fourteenth edition. London: J. and A. Churchill. 1907. Pp. 273. Price 5s. net.—The success which has attended this book, measured by the sale of 28,000 copies since its production in 1884, is justified by its excellence. Though we are in favour of impressing upon the student that he is not qualified to order glasses for the correction of errors of refraction until he has devoted special time to this branch of ophthalmology and has already had large experience under expert supervision we are yet of the opinion that he should thoroughly master the principles, since they form the basis of a skilful use of the ophthalmoscope. If the average student's manual were less like a *précis* of the advanced text-book and more attention were paid to the elaboration of fundamental principles we think that this type of monograph would lose its *raison d'être*. In the meantime we commend this particular specimen of a too luxuriant class on account of its clearness, accuracy, and absence of individual foibles.

Photoscopy (Skiascopy or Retinoscopy). By MARK D. STEVENSON, M.D., Ophthalmic Surgeon to the Akron City Hospital, Ohio, &c. London and Philadelphia: W. B. Saunders Company. 1906. Pp. 128. Price 5s. net.—The author of this book acknowledges in the preface his indebtedness to the works of Jackson and Thorington on the same subject. It is to be regretted that, having read these works, he did not appreciate the fact that his own book was redundant. He has added nothing of importance and, in our opinion, he has not succeeded so well in describing the test. It is possible that the expert ophthalmologist might meet with a few suggestive statements, but the book is obviously not written for him. The student will, we fear, be confused by the manner in which salient points are jumbled together with comparatively trivial details. From the first page throughout the book the term "anterior focal point of an eye" is wrongly defined and used in a misleading manner. The anterior focal point of the emmetropic or axially ametropic eye is a definite point situated about 13 millimetres in front of the cornea. The author's use of the term and the confusion which necessarily arises are well exemplified in the following short paragraph: "Our object in photoscopy is to locate the anterior focal point of an eye, or, in other words, the place where light rays reflected from the retina focus or cross. In myopia they focus without the aid of lenses, but in all other conditions lenses are required to obtain an anterior focal point. By the use of lenses the location of the anterior focal point can be changed." In myopia the anterior focal point is said to be "at once the far and (unless the eye accommodates) near point of the eye." These quotations will suffice to show that the author is not a very safe guide to the theory of retinoscopy. A chapter is devoted to the history and name of the test. Dr. Stevenson might have spared us another christening of this multinominate bantling.

The Sigmoidoscope: A Clinical Handbook on the Examination of the Rectum and Pelvic Colon. By P. LOCKHART MUMMERY, B.C. Cantab., F.R.C.S. Eng. London: Baillière, Tindall, and Cox. 1906. Pp. 86. Price 5s. net.—This monograph belongs to the necessary class of such publications; it is a simple and lucid account of the electrically illuminated pneumatic sigmoidoscope, the method of its use, and the appearances which it makes visible. The instrument is of hardly less value than the cystoscope, and although, as Mr. Mummery writes, practical experience is a *sine quâ non* to its successful use, the book will afford a valuable preface to such practice. It would be of value if it only contained its healthy warnings against the abuse of the sigmoidoscope, the chief of which are the passage of the instrument by feeling instead of sight and the too liberal employment of the pneumatic inflator. After the description of the technique of the use of the sigmoidoscope and the appearance of the healthy bowel, the changes seen in cancer and the various inflammatory and ulcerative conditions of the rectum and pelvic colon are described and are illustrated by some useful plates. If in a subsequent edition these could be replaced by accurately coloured pictures we venture to think the value of an excellent monograph would be enhanced.

JOURNALS AND MAGAZINES.

Annals of Ophthalmology. Edited by WILLIAM T. SHOEMAKER, M.D., and C. W. PARKER, M.D. Vol. XVI. No. 1. St. Louis, Mo., U.S.A.: Jones H. Parker. 1907. Price 18s.—The present number of this journal opens with an article under the name of Dr. A. Darier of Paris, which is entitled "Intravenous Injections." Dr. Darier claims for this mode of therapy freedom from pain, rapid, certain and exact action, and absence of local lesions and of late secondary effects. Cocaine should not be used. The solution he recommends for intravenous injection is hydrargyri cyanidum 0·33 gramme, sodii chloridum 0·08 gramme, sodii phosphas 0·07 gramme, and aquæ destill. et steril. 100 cubic centimetres, of which two or three minims should be slowly injected into a vein at the bend of the elbow. 2. Dr. J. H. Woodward of New York writes upon the *Ocular Complications of Mumps*. The chief affections mentioned are optic neuritis and atrophy, iritis and iridocyclitis, affections of the annexes of the eye, neuro-muscular complications, and lesions of the fundus. In an appendix to this article is given a list of authors who have contributed important papers on this subject. 3. *A Case of Bilateral Metastatic Ophthalmitis in Puerperal Pyæmia, followed by recovery*, by G. E. de Schweinitz, M.D. 4. *Fundus Lesions with Normal Vision*, by J. F. Burkholder, M.D., of Chicago.

CASES.

Vulva.

CASE 1 (under the care of Dr. W. S. A. Griffith).—A female, aged 67 years, was admitted to Martha Ward in St Bartholomew's Hospital in July, 1897, suffering from a raw, moist growth on the inner aspect of the right labium majus, of the size of a five-shilling piece and half an inch in thickness, of a year's duration. It was freely cut out on August 6th. Shortly after the operation she began to suffer from irritation of the left labium majus, and in October she noticed a lump there. She was seen by Dr. Griffith in November and advised to have the lump removed, but she would not enter the hospital until January, 1898. There was then an ulcer of the size of a shilling. The scar on the right labium was quite sound. The disease was cut out on Jan. 7th. Both the growths showed the typical characters of squamous carcinoma. Owing to the many years which have elapsed since this patient was under care I have found it impossible to obtain such information as I could have desired regarding the exact seat of the second growth, whether it was just opposite the seat of the primary disease; so the case is not wholly complete

CASE 3.—In December, 1905, Miss L. B. Aldrich-Blake removed an epithelioma of the left labium of a woman who was 53 years old. It was of several months' duration and was situated a quarter of an inch below, and one and a quarter inches to the left of, the orifice of the urethra. It proved to be a squamous carcinoma. During the time the patient was in the nursing home she complained of soreness of the other labium, opposite the seat of the ulcer, but no lesion was discovered. In October, 1906, she again came under the care of Miss Aldrich-Blake for a circular, flat, hard patch on the right labium, exactly opposite the spot where the ulcerated cancer had been removed from the left labium. She said that she had never lost the sensation of discomfort of which she had complained when she was in the home and that she had noticed that the place was growing hard for the last four months. The plaque was removed and was found to be a squamous carcinoma. I have here photographs of the microscopical characters of the disease on both sides, which were admirably taken by Miss Debenham. They are the more valuable because they show the exact limit of each growth and the healthy tissues beyond its margin.

Larynx.

From my laryngological friends I received many letters, the very large majority of which were to the effect that the writers had never seen a case of auto-inoculation. On the other hand, I can report three cases in point.

CASE 6.—In the Transactions of the Clinical Society for 1889[1] Dr. David Newman of Glasgow described the case of a man, aged 49 years, who suffered from an elevated ulcer of the left false cord midway between the anterior and posterior attachments. Dr. Newman watched the case at the Glasgow Infirmary. In the month of June, 1887, he observed a localised redness of the right false cord, limited to a point where the free surface of the tumour impinged upon it. In spite of careful treatment an ulcer formed at this spot in the month of December of the same year and soon attained a larger size than the ulcer on the left false cord. The tissues in front of, and behind, the ulcers were free from disease, so that there was no continuity between the growths. The patient died in April, 1888, when two ulcerated tumours were found, one on each false cord, extending forwards towards the commissure so as almost to meet in the middle line in front, but there the continuity was broken. Microscopic examination of the tumours showed them to be epitheliomata.

CASE 8.—In February of this year (1907) I went to see an old man with Dr. Boyd of Victoria Park in consequence of a communication which was made to me by Dr. Hunter F. Tod. The patient was suffering from extensive disease of the larynx, the right half of which was swollen almost throughout, but chiefly at the posterior end of the true cord, where there was prominent ulceration. The left true cord was diseased from end to end, but the growth was most prominent and ulcerated immediately opposite to the most prominent ulcerated disease of the right cord. There was undoubted continuity of the disease in front. Dr. H. Lambert Lack had examined the patient three months previously and he told me that the left cord was free from disease at that time. Two months later, when the patient was first seen by Dr. Tod, there was a growth on the left cord, at the point where the disease was most developed when I saw him, and the forepart of the cord was free from the disease. After the patient's death the growths on both cords were examined by Dr. F. W. Andrewes who found that both of them presented the typical characters of epithelioma. If this patient had come under observation for the first time in the month of February probably there would have been no suspicion of auto-inoculation and the occurrence of the disease on both sides would have been attributed to continuity of growth. This case suggests that some of the cases in which there is advanced disease on both sides of the larynx, with continuity in front particularly, may really have been cases of auto-inoculation, the first stages of which had not been observed for want of opportunity.

In this relation I would mention a case of which Dr. H. Tilley told me of a patient whom he exhibited seven years ago at the Laryngological Society. Dr. Tilley removed an epithelioma of the anterior third of the right vocal cord. The left vocal cord, immediately opposite to the epithelioma, was raw, as if it had been "chafed" by the growth, but it bore so suspicious an aspect that the anterior third of the cord was also removed. The sore place was examined microscopically, but showed only "heaped-up epithelium and signs of inflammation in the deeper tissues." Had the disease been allowed to continue unoperated for a little longer epithelioma might have developed, as in the case related by Dr. Newman. Once more the necessity of microscopical examination is demonstrated, for the naked eye took a more serious view of the nature of the sore than was warranted by the histological examination.

Lips.

In the course of an important discussion on cancer which took place in Glasgow just over 20 years ago[2] Sir Hector C. Cameron expressed an opinion unfavourable to auto-inoculation. As a part of his argument he said: "The upper lip in every case of epithelioma of the lower lip is in close contact with the disease by night and day. Moreover, the prolabium is even a more favourable surface for contamination than the skin. But has anyone ever seen the upper lip become affected by direct contamination under such circumstances? That it is capable of becoming affected is shown by the fact that an epithelioma of the lower lip not infrequently extends to the upper, round one or other commissure." Since that discussion took place two or three cases have been reported but not one of them was confirmed by microscopical examination until recently. I am now, however, able to furnish one complete example.

CASE 9.—In November, 1887, Professor von Bergmann showed to the Berlin Medical Society a man, 66 years of age, with a cancer of the middle of the lower lip. It was ulcerated. In the upper lip, exactly opposite to it, was a similar disease. Each was of about half the size of a hazel nut. The tumour of the lower lip had been noticed for three months and the tumour of the upper lip began to form six weeks later, soon after the first tumour became ulcerated. That case has been quoted on many occasions, and Kirmisson a year later said that he had had a similar case in his own practice. But neither of these cases appeared to have been examined microscopically, so that the just objection might have been raised against them that there was no proof of the precise nature of the ulcer of the upper lip. I sought in vain for a further report of von Bergmann's case but did not succeed in finding it. In January of this year, therefore, I wrote to him and received the following reply: "I removed both epitheliomata and examined them microscopically. They were unmistakeable epitheliomata" ("Beide Epitheliome habe ich excidirt und microscopisch untersucht. Sie waren deutliche Epitheliome").

There is thus one undoubted case of contact epithelioma of the lips. I also communicated with Professor Kirmisson but received no reply from him, so that I must conclude that his case was not microscopically investigated.

If it be wondered why auto-inoculation of cancer of the lip is so very infrequent I would point out that there are several reasons why this should be so. The upper lip is notoriously unfavourable to the development of primary carcinoma. It course of an operation if the pad becomes soiled it can be removed from the abdomen and the rubber sheet inserted in a fresh sterilised covering, a number of which are kept ready at hand. In suturing the abdominal wall it very effectually protects the intestine and omentum from becoming caught in the sutures and can, owing to its elasticity, be easily removed through as small an opening as a marine sponge. The advantages claimed for it are: 1. The ease with which it is rendered aseptic. All that is necessary before using is to boil the rubber and as many bags as may be required in the steriliser. They can then be used as they are or placed in lotion previously according to the method of the operator, contrasting favourably with the tedious and difficult cleansing of marine sponges. 2. It overcomes the difficulty often experienced in using plain gauze or gauze-covered wool pads of their becoming wrapped upand entangled in the omentum and coils of intestine, nor does it leave behind small particles of wool to interfere with healing. 3. It is unaffected by ordinary antiseptics. 4. By reason of its elasticity and moderate rigidity it effectually prevents the intestine from obscuring the field of vision, especially in deep operations in the pelvis or in the region of the gall-bladder. The rubber sheets are made in different sizes, each with a number of covers; the size I find most convenient for general use is 7 inches by 8 inches. The pads completed may be obtained from Messrs. Mayer and Meltzer who have carried out my suggestion in a neat and efficient manner.

G. W. KILNER CROSLAND, M.R.C.S. Eng., L.R.C.P. Lond.,
Honorary Surgeon, Huddersfield Infirmary.

"THE WATCH-POCKET" ASEPTIC HYPODERMIC SYRINGE.

Messrs. Allen and Hanburys have submitted to us an all-metal hypodermic syringe which has some new features that should recommend it to the medical profession. The plunger is of metal, with engraved minim graduations; the top and bottom mounts are fitted with bayonet catches instead of screw threads, thus insuring easy sterilisation, things which go to make up a simple and trustworthy instrument, but which other inventors have equally made use of. The really novel device is in connexion with the needles, six of which are contained in a sterilised glass tube which fits inside the hollow metal plunger; the head of this part is made broad so as to allow of the syringe standing upright on it whilst a "hypodermic tablet" is dissolving in the barrel. The instrument is inclosed in a neat plated metal cylindrical case three inches long, with a ring to affix to a chain. Its price is 10*s*. 6*d*. with six needles; spare tubes containing six sterile needles are sold for 1*s*. 6*d*. per tube, or with platinum iridium needles for 7*s*. 6*d*. per tube.

MEDICINE AND THE LAW.

"*The Usual Medical Attendant.*"

INSURANCE offices are entitled to the opportunity of consulting with the medical man who has been last in attendance on the insured. No doubt the most perfect *bona fides* is to be observed in life insurances as in other contracts; and should the referee make a wilfully untrue statement or collude with the party making the proposal, he may, although not personally interested in the contract, render himself liable to an action if loss should ensue; for if a man will wickedly assert that which he knows to be false and thereby draws his neighbour into a heavy loss, even though it be under the specious pretence of serving his friend, he makes himself liable for the damage, and that even if no fraud was intended by him. A statement false in fact, but not known to be so by the party making it, or not made with intent to deceive, but, on the contrary, believed to be correct, will not render him liable in an action, although it may have induced the insurers to undertake the insurance and they may have suffered pecuniary loss thereby, since to support an action of deceit the scienter must be proved. In Wheelton *v.* Hardisty (5 Jur. N.S. 14) the court decided that "in cases where the representations of the referees are made the basis of the policy the answers of the referees are binding upon the insured, so as to make the falsehood of their representations an answer to an action on the policy, but in the present case, considering that the parties insuring were only required to state their belief as to the matter under discussion and that the life and referees were really acting in fraud, both of the plaintiffs and the defendants, and that they were not at all in the capacity of persons negotiating the contract, we can see no pretence for making them the agents of the parties insuring, so as to render their fraud that of the plaintiffs. The insurer and the insured being equally ignorant of material facts to influence their contract, if the insurer asks for information and the insured does his best to put the insurer in a situation to obtain the information and to form his own opinion whether the information is sincere, can it be permitted that when the insurer, without any blame being attributed to the insured, has allowed himself to be deceived he shall be able to say to the insured, 'you warranted all the information I received to be true, and having received your premiums for many years, now the life drops, I tell you that I was incautious and the policy I gave you a nullity'?" All insurance offices are naturally desirous to consult with the medical man who has been last in attendance on the life to be insured; and when the reference was made to a person who had been the ordinary medical adviser, but no mention was made of the person attending at the time of the insurance the policy was vacated. At the same time a reference to a person who, immediately before the time at which the policy is effected, has been casually consulted for trifling maladies, will not satisfy the requisition for a reference to the *usual* medical attendant, although the person who had formerly attended may have retired from practice at the time. "Who is your usual medical attendant?" involves a question of considerable importance. "Now," said Lord Abinger, in Hackman *v.* Fernie (3 M. & W. 505), "let it be considered for a moment what is the grammatical sense of the question. It is in the present tense. Suppose a person goes to effect a policy on his life who had no medical attendant in the last year; if the answer to the question were, 'I have no such medical attendant,' must not that question of necessity be followed by another question, which is, 'Who was your former medical attendant?' The terms and nature of the question show that it was designed to extract from the person who is the medical attendant, best able to give an account of her constitution at that time; and if she has no medical attendant in the precise grammatical sense of the question, it appears to me that she is bound to mention who is the medical attendant who could give that information." Also, "the word 'usual,'" said the same authority, "implies having attended more than once." In Everitt *v.* Desborough (5 Bing. 503) the plaintiff, wishing to insure the life of a man named House, referred the agent of the company to him for the necessary information for filling up the declaration, and he stated: "I have never had occasion for a doctor: sometimes I have taken Harvey's quack pills, but Mr. V. knows as much of me as any man." The agent therefore drew up the proposal, which was signed by the plaintiff, stating that Mr. V. was the usual medical attendant. It was proved on the trial that Mr. V. had not attended House for nearly 20 years, but that he had been occasionally attended after fits of intemperance, in which he was wont to indulge, by a quack doctor named Harvey. Of this the plaintiff was unaware. The court decided that it was no matter whether Mr. Harvey was a good medical attendant or not, he was the person actually attending him; that the circumstance that the plaintiff was ignorant of the error did not affect the question, but that the policy was void. Hence, it seems that it is not necessary that the usual medical attendant should be a regularly qualified practitioner; the person who acts in that capacity, whether qualified or not, is the person to give the required information.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM, N.—A vacation course will be held at the hospital during the coming September, commencing on the 9th of that month, the arrangements for which have been adapted to the requirements of those engaged in active practice. They include daily cliniques in the wards, demonstrations in the out-patient departments, classes on clinical methods, other practical clinical demonstrations, and clinical lectures with lantern demonstrations. The fee for the course, which will last a fortnight, is 1 guinea. Further particulars may be obtained from the Dean at the hospital.

without notice one point of practical importance, the possibility of wound infection in operations for cancer. For some years past surgeons have been more cautious than they used to be in dealing with cancerous growths, and many cases have been recorded in which there was reason to believe that recurrence was due to implantation during the operation rather than to imperfect removal of the disease. Ten years ago Dr. Lambert Lack wrote on this subject a paper which was published in THE LANCET[3] and described cases, of which he had made the microscopical examination, which threw the gravest suspicion on instruments and the tearing of breaking-down cancers as the cause of immediate recurrence of the disease. I think his cases are some of the most conclusive I have read in this regard and the possibility of the occurrence must never be lost sight of. Cancers should not be cut into unless for diagnosis and the wound should be tightly closed before the actual operation is commenced. The instruments which were used for the purpose of diagnosis must not be used again until they have been boiled. Exposed or ulcerated cancers should not be pressed against or dragged across raw surfaces made in the course of the operation. And care should be taken that breaking-down cancers are not opened during operation. If they are opened by mischance means should be taken to cleanse the surface of the wound and to destroy the exuded contents of the cancer cavity.

In the early part of this address I stated that the study of auto-inoculation is, for me, only preparatory to the study of the communicability of cancer from one human being to another. And I have set myself the task of investigating this question. That it is an exceedingly difficult investigation there can be little doubt. And from what has transpired in the course of this address there can be even less doubt that such cases must be very rare. The small number, if there are any such cases, must be compensated by the quality of those which are discovered. I have thought out the conditions in which contagion is most likely to take place and have come to the conclusion that coition is the most likely of all conditions to place either the male or the female in danger of contracting cancer. The organ of the male and the os uteri of the female are frequently the seat of cancer. These parts are subject to the same variety of cancer, squamous carcinoma, although the uterus is also liable to cylindrical carcinoma. Cases of coition-cancer have been from time to time reported. But they are very few in number and I have not yet discovered one of them in which the essential conditions are fulfilled. The remark has frequently been made that, if cancer is contagious in the human subject, cases of coition-cancer ought to occur with some degree of frequency. I do not think so, for the following reasons: The presence of an ulcerated cancer in the male would render him disinclined to coition, so that the female would be but rarely exposed to contagion. The cancer of the female is generally septic when it is exposed (that is, ulcerated), and unless it is ulcerated the disease is not likely to be communicated; although coition is known to take place even in the presence of an exposed carcinoma of the uterus it is not likely to be frequent; ulcer or excoriation of the male organ, which is probably almost essential to contagion, is a condition which deters the male from coition. Again, auto-inoculation is probably rendered more easy by the fact that the patient is more or less prone to the occurrence of cancer. And, if there be persons who are prone to a disease it is reasonable to suppose that there are other persons who are much less prone to it, or even immune. They possess a resisting power against the disease which it may be impossible to overcome, or which can only be overcome with difficulty. Far, then, from wondering at the rarity of reports of coition-cancer, I should be surprised if they were more frequent. Yet I believe they do occur, and Mr. R. B. Etherington-Smith (who has been assisting me in this investigation and to whom I am already much indebted) and I are devoting our attention to the discovery of cases in which cancer may have been communicated by coition. One of the chief reasons which led me to choose the subject of this address was the hope that the publication of it might assist us in finding some of the cases we are seeking; for they are more likely to fall under the observation of those who are engaged in general practice and are acquainted with the histories of their patients than under the observation of those who, like myself, are engaged in a special branch of our profession. And I think they are more likely to be recognised among patients in higher than in lower social conditions.

Postscript.—In the foregoing it will at once be apparent to those persons who have made a study of this subject that I have not used all the cases (which fulfil the essential conditions) which may be collected from surgical literature. I preferred to use only a few cases, provided I knew something personally of them or could obtain special information regarding them, and I have only used some of the old published cases on account of the excellent reports which belong to them or to fill in gaps. Again, it will be noticed that I have made no mention of cases of reputed contact-cancer of the bladder or of the intestine. I have left them out, not because they did not appear to me to be true examples of contact-cancer but because objections might be raised against them which could not be made in most of the cases I have described. It is probable that I shall soon publish a much larger number of cases and introduce a good deal of material which would not serve as a proper foundation for the proof of auto-inoculation but which will serve as an excellent superstructure.

MOBILE KIDNEY, WITH A DESCRIPTION OF AN OPERATION FOR ANTERIOR NEPHROPEXY.[1]

BY E. STANMORE BISHOP, F.R.C.S. ENG.,
HONORARY SURGEON TO THE ANCOATS HOSPITAL, MANCHESTER.

IT will be agreed, I think, to start with, that true floating kidney—that variety which possesses a mesonephron and is entirely surrounded by peritoneum—is a thing of great rarity. Sir W. Jenner, in his lectures on abdominal tumours, says that he once felt a mass which was supposed to be one during life but had never met with one in all his post-mortem examinations. In my search through the literature of this subject I have come across three undoubted specimens, but besides these I have been unable to find any others recorded. The condition must, therefore, I conceive, be regarded as a surgical curiosity. The cases in which we as practical men are interested fall into the category of "mobile" or "wandering" kidney; they are not surrounded by peritoneum and their excursions take place entirely behind the parietal peritoneum in the loosened subperitoneal connective tissue.

Confining ourselves, then, to this variety, it will be seen on further examination that only on four points do all writers on the subject appear to be agreed. These are: (*a*) that such a condition does actually exist; (*b*) that this condition exists most frequently in women (Newman estimates the proportion at 86·2 per cent., Landau at 88·9 per cent., Longyear at 85·0 per cent., Schutze at 85·0 per cent., Küster at 90·9 per cent., and Skorczewsky at 91·1 per cent.); (*c*) that it is most frequently seen on the right side (Goodhart estimates the proportion at 80·0 per cent., Longyear at 93·7 per cent., and Landau at 84·8 per cent.); and (*d*) that it is very frequently associated with neurasthenia. When one examines further still, however, all agreement disappears, and the widest differences are found. Nothing, for instance, is more striking than the different estimates of the frequency of this affection by different authorities. Thus Lindner finds a moveable kidney in every third or fourth woman who comes for examination; Oser, of Vienna, said that in Austria 10 per cent. of all women who have borne children are affected; Edebohls found 90 cases in 500 women, and Matthieu 45 in 306 women. On the other hand, Skorczewsky found only 31 women in 1030 and three men out of 392, or 34 out of a total of 1422. Ebstein, in the Charité in Berlin, found only five cases in 3652, and Rollet, in Oppolzer's clinic, found 22 in 5500, whilst Sir Andrew Clark had only seen two cases in 4000 bodies examined post mortem. Mr. H. Morris, in the Cavendish lecture of 1893, remarked upon this variation in the evidence as to the frequency of this condition, and two years later, in 1895, Sir Kendal Franks repeated the observation.

Even more remarkable, if possible, is the difference of opinion as to the importance of this displacement when found. In 1895 Sir Kendal Franks said that the tendency of the medical mind at that time "was to assert that for the good will be obtained from physical exercises and the possibility of harm from them prevented. The utility of the next measure that he advocates entirely depends on the thoroughness and accuracy of those responsible for its administration: we refer to the medical examination of school children with a view to the control of their work and play. Dr. DAVY quotes the example originated by Dr. C. DUKES at Rugby School as a model for the system which should be adopted; such a system must depend on the thorough examination of each child, the methodical record of its result, and the subsequent observation of the course of work and play allotted, with a view to the attainment of that accurate science of educational hygiene which the International Congress to be held next week in London aims at constructing. Dr. DAVY insists on the importance of giving school children some knowledge about the structure of their bodies, and the justification of this measure, which we have systematically advocated, is simply that they may be given an accurate basis on which to found the physical conduct of their lives, instead of having to rely upon such haphazard and slipshod notions of the "laws of health" as their parents may or may not see fit to impart to them. The end of the address under review gives a striking object lesson from Japan, where the training of the medical profession in accurate methods has led to an equally scientific spirit of hygiene being widely spread through the country.

[1] A paper read before the British Gynæcological Society on March 14th, 1907.

Turning now to Mr. BUTLIN's address in Surgery we are reminded of the hopeful fact that there is a growing national appreciation of the necessity of accurate and patient research into all the great mysteries of disease. The systematic manner with which the problem of cancer is being investigated is largely owing to public interest, and of this method of research Mr. BUTLIN's address forms an excellent instance. He has set himself the task of investigating the possibility of the contagion of cancer in human beings, and it has occurred to him that the establishment of the occurrence of auto-inoculation of a non-cancerous part of a cancerous patient's body by direct contact with the cancerous part will be an important step towards demonstrating the possibility of the contagion of the disease between different persons. He first formulated certain stringent conditions to which every case must conform before he would admit the occurrence of auto-inoculation as proved for it, and then with extreme care he investigated the facts of all such cases to which he could gain access. This research is an apposite example of the advantage of accurate observation for the cases depend in many instances for their validity on the recording of the exact spot, sometimes within a fraction of an inch, at which the supposed auto-inoculated tumour started. It should be a stimulus to accurate habits in all clinical recorders, especially those who are working at hospitals where the case-papers for which they are responsible will be filed for reference, never to describe a phenomenon in writing unless they have for it the evidence of their own senses, for a neglect of this principle may render them guilty of mercilessly misleading some future inquirer. Mr. BUTLIN has been happy in being able to assure himself of the accuracy of the records which he quotes, and they make a strong case in favour of the auto-inoculation of cancer; we trust that they will serve to lead him and his fellow explorers in this dark country many steps along the road.

The Qualification for the Office of Physician in Provincial Hospitals.

WE published in THE LANCET of July 20th, p. 203, a note on the recent decision of the governors of the Hastings, St. Leonards, and East Sussex Hospital to rescind the rule which made it obligatory for a candidate for the office of physician at that institution to hold the Membership or Fellowship of a College of Physicians. The rule has now been changed so as to allow a medical graduate of any British University to fill such a post, and no restriction will be placed upon the class of private practice which may be conducted by the physicians of the hospital. The matter opens up considerations of far wider import than is at once apparent, and in calling attention to a few of them it will be as well to mention briefly the decisions which within the last two years have been reached by the governors of the Royal Berkshire Hospital and of the Cheltenham General Hospital respectively when called upon to give their verdicts in similar contingencies to those which have recently occurred at Hastings. Events at the Hampstead General Hospital, which we have reported, may arise in this connexion in some of our readers' minds, but as there are here other issues we propose only to discuss the simple case as it has occurred at the provincial hospitals which we have mentioned.

At the Royal Berkshire Hospital the rule for the office of physician originally provided that the holder must be a medical graduate of Great Britain or Ireland, and that he should not practise, or be connected in partnership with anyone practising, surgery, pharmacy, or midwifery. This meant that although the Hospital did not insist on its physicians holding the Membership or Fellowship of a College of Physicians (to which we may conveniently refer as the "Membership qualification"), yet it did insist that they should be exponents of pure medicine, in its limited sense, and as such presumably skilled above the ordinary in its practice. There is nothing in the rule to indicate that they should be what was originally meant by the word "consultants"—i.e., that they should only see patients in consultation with other practitioners. In the autumn of last year two assistant physicians were appointed at the Royal Berkshire Hospital whose private practice did not conform to this rule, the sanction for their election being provided by a deletion of the clause forbidding the practice of midwifery. At that time[1] Dr. FRANCIS HAWKINS wrote to ask for our opinion as to whether this was fair treatment of the physicians appointed under the former restriction, and we replied that, if in the opinion of the authorities the change was of the nature of a reform which they believed would be for the good of the institution which they administered, it was right that it should be made. We also said, as we still hold, that "any modification of hospital rules which tends to break down generally held opinion that the kidney is maintained in its position by the combined and interacting pressure of the various abdominal viscera. Professor His and Professor Cunningham have described and figured a central transverse mound or ridge which they found on the anterior surface of kidneys artificially hardened *in situ* and which they consider is produced by the opposing pressure of the various organs lying in contact with them. "The impressed districts," they say, "lying above and below indicate pressure applied to the anterior surface in two directions, and the intervening eminence is the result of this counterpressure."

---

[1] THE LANCET, Sept. 8th, 1906, p. 678.

None of these, however, explain the great and universally admitted preponderance of dislocation on the right side, nor am I aware of any serious attempt at such explanation until Hutchinson, jun., drew attention to the existence of Toldt's fascia on the left, and its absence on the right side, as well as to the manner in which the splenic flexure lay over and was fixed to the anterior surface of the left kidney, whilst the hepatic flexure remained free and lay entirely below the right. Both of these restraints lie, however, above the peritoneum, which can still be loosened behind them by a descending kidney.

Much more to the purpose appear to be the observations of Longyear in the *American Journal of Obstetrics* of November, 1905. This writer describes a tendinous attachment between the lower pole of the kidney and the colon below. This is formed, he says, by the gathering together of longitudinal fibres from the fibrous network forming the framework of the fatty capsule; this band or cord could be followed downwards between the peritoneal reflections to the margin of the lower peritoneal attachment of the bowel close to the ileum and was probably the tissue left in the track of the ovary in its descent from its place of origin in the Wolffian body. These fibres unite with the posterior longitudinal band of the colon on both sides with that of the ascending colon on the right and that of the descending colon on the left. When the ascending colon contracts upon its contents it pulls, so Longyear says, upon this band and through it upon the kidney in a downward direction. When the descending colon contracts, on the other hand, the pull is exerted in the reverse direction—that is, in a direction upwards. If this description is correct it is easy to understand why the right kidney should be so much more frequently displaced and the existence of this connexion has an important bearing upon the question of operative treatment, as will presently be seen. In connexion with this it may be noted that Nagel describes the ligamentum suspensorium ovarii as springing developmentally from the phrenic ligament of the kidney, and being therefore situated on the posterior abdominal wall. In addition Newman has described what Barthol calls the ligamentum suspensorium renis—a number of fibres with well-marked attachments above to the diaphragm and internally to the spinal column, but with vague terminations below and outside. These fibres must end somewhere, and it is at all events possible that they may end as Longyear describes.

Whatever view is taken of the causation of wandering kidney it is evident that the factors producing the displacement act unequally upon the two equally important segments of this part of the urinary apparatus, the kidney itself and the peduncle composed of its ureter and the vessels passing to it from the aorta and vena cava. Whether loss of supporting fat, alterations in the incidence of intraperitoneal pressure, or undue traction upon the lower end of the ligamentum suspensorium renis, all will act with much greater and more immediate force upon the kidney itself, and it will only be after these factors have been in action for some time and have begun to be reinforced by the *added* weight of this organ, that any alteration will be perceptible in the attachment of the ureter to the spinal column or in the length of the vessels.

Two stages in the descent of a "wandering" kidney are therefore predicable from the very conditions present, and the history of reported cases proves not only that such stages do occur, but that they are easily recognisable, the symptoms present in each being markedly different. In the first stage the kidney itself tends to sag downwards, the lower pole becoming recognisable by the examiner's hand on a lower and more median plane than normal; the vascular peduncle being, however, of a normal length, the actual position of the organ will be that of the resultant of the two forces acting upon it—loss of support, aided by any other force pulling downwards, and the inward pull of the vascular and ureteral peduncle; it will consequently rotate in the line of a curve the centre of which will be the most fixed point of its attached vessels; this is the stage described by Morris as a distinct variety, the "cinder-shifting" variety. The symptoms of this stage are such as might be expected from the mechanical condition; the bend produced at the junction of the renal pelvis with the ureter, produced by the rotation of the kidney, will interpose a distinct obstacle to the due evacuation of urine from the renal pelvis and the renal intra-pelvic distension so caused will result in "aching and tenderness in the renal region of the affected side." If the bend be an acute one and somewhat suddenly made Dietl's crises will be present; these depend not only on the ureteral obstruction but also, and perhaps mainly, upon the kinking or twisting of the renal veins which necessarily accompanies it; these crises are characterised by "violent attacks of colic, attended by nausea and vomiting, possibly abdominal distension and tenderness, sometimes by a rise of temperature and collapse" (Morris).

Arbuthnot Lane[2] says that torsion such as is found in the case of an ovarian pedicle cannot possibly occur, and there can be no doubt that in the true "wandering" kidney this is correct, since sufficient room for this to take place does not exist, but it is certainly true that the renal veins may be so bent over the more resistant structure of an accessory renal artery when that exists, or over the spinal attachment of the ureter, in consequence of the quick curve described by the kidney in its descent, as gravely to obstruct the flow of blood in them. Lane has noticed that in these cases the lower end of the kidney comes forward in front of the ureter; the main axis of the kidney from being vertical becomes horizontal; the ureter thus becomes bent over the body of the kidney itself. Newton Pitt says that the ureter may become sharply bent over an aberrant inferior renal artery. In whatever way this result is produced, "temporary anuria, followed later by an unusually free flow of urine," will in such cases be a notable symptom.

Digestive disturbances, nausea, dyspepsia, vomiting, and jaundice, have been frequently observed*, as to their mode of production, opinions differ. Lane thinks they may be due to dragging upon the renal plexus or to direct displacement of the vertical part of the duodenum. Dr. Maclagan recorded in THE LANCET three cases of jaundice which he believed to be due to the direct pressure of displaced kidneys upon the cystic duct.[3] Presumably the common duct is meant. Morris, with more probability, attributes such symptoms to the dragging downwards of folds of peritoneum which pull upon the duodenum or gall-ducts; he has noted that traction forwards and downwards of a right kidney pulls upon the duodenum at a point two or three centimetres below the entrance of the biliary duct. He does not believe that direct pressure upon the bile-ducts is ever produced by a floating kidney, and if by that term is meant a "wandering" kidney—for these terms are used indiscriminately by various writers—it is difficult to see how it could be, the movements of such a kidney, however free in the vertical and horizontal planes, being always restricted by the peritoneum from any marked excursion in the antero-posterior plane, whilst the gall-ducts, unless bound down by adhesions, are capable of almost unrestricted movement in that plane, and could therefore always escape.

It will have been noticed that the symptoms so far enumerated are almost all of an acute type; moreover, that they occur early in the history of those cases in which they appear; consideration of their mode of production readily explains this. It is unfortunate that in precisely the same cases and for the same reason the recognition of the displacement is the most difficult; inasmuch as the peduncle has not yet become elongated, the actual descent of the kidney is necessarily restricted and, especially in stout people, may be very difficult to recognise; indeed, a diagnosis may be only possible by exclusion, or even, as Morris observes, by exploratory operation.

In the second stage, owing to the persistent action of the downward traction, whether this be due simply to the unsupported weight of the kidney itself or, as Longyear believes, to the pull of the colonic connexion, the attachment of the ureter to the spinal column becomes looser, is elongated, and permits more range of movement; at the same time and from the same causes the vessels gradually elongate and become less firmly attached to their surroundings; both these conditions act and react upon one another,

[3] Transactions of the Medical Society of London, vol. xxv., p. 59.

It is noteworthy that during the same period the number of fatal mining accidents has steadily diminished owing to the greater care exercised in regard to the use of explosives and to the supply of safety appliances. The great increase in the death-rate from tuberculous disease, Dr. SUMMONS maintains, clearly shows that the same concern is not manifested in the maintenance of the miner's health as for his safety. It is generally admitted that one of the main factors in this increased mortality has been the introduction of machine rock-drills which have enabled mining operations to be carried on with much greater rapidity but with the production of a greatly increased amount of dust. Dr. SUMMONS summarises the clinical features as observed by himself in 192 cases of "miner's phthisis" in all stages. The onset is most insidious and, as a rule, only after years of work in the mines are symptoms apparent, such as frequently recurring coughs and mild attacks of bronchitis, the general health remaining good or, at any rate, such slight malaise occurring that there is no interference with the men's capacity for work. Even before tuberculous infection is superadded the expectoration may be profuse, muco-purulent in character, and teeming with staphylococci and putrefactive organisms. Often it is coloured by the dust particles constituting the "black spit." Sooner or later the affected miner complains of shortness of breath, greatly augmented by the attacks of bronchitis, and this condition increases till he is quite incapacitated for work, the slightest exertion producing hurried breathing and stridor. This dyspnœa is not associated with any signs of cardiac weakness and does not cause cyanosis. Such is the usual history of a case of pure fibrosis, the general health remaining satisfactory and the appetite good; a few of the patients, if kept from going to the mines, improve but are unable to carry out any occupation requiring exertion. They usually show an increase in the number of red blood corpuscles with a high percentage of hæmoglobin. Associated with the bronchitic attacks there are as a rule pleuritic pains and generally signs of pleurisy are discoverable, notably in the region of the fifth and sixth ribs in the axillary region. On physical examination of an ordinary case of fibrosis the hurried breathing and diminished chest expansion are noticeable and the vocal fremitus is often increased but local areas of diminution are not uncommonly found. Dulness, especially towards the bases and in the axillary regions, results from pleural adhesion and from the fibroid changes in the lungs. The auscultatory signs comprise prolongation of expiration and various degrees of bronchial breathing, with signs of bronchitis and also creaking sounds audible on inspiration and expiration. Cardio-respiratory sounds, especially a series of short puffs synchronous with the heart beats, are common as also are fine pleural friction sounds.

As already pointed out, with such signs there may be little or no constitutional disturbance; the disease is purely a local disease of the respiratory organs, with respiratory symptoms only. When, however, tuberculous infection develops there are progressive weakness and loss of weight, with drenching night-sweats and a slight rise of the evening temperature. The symptoms show some slight variations from those of ordinary pulmonary tuberculosis—viz., hæmoptysis is rare owing to the peri-bronchial and peri-arterial fibrosis, and pneumothorax is extremely uncommon owing to the pleural adhesion which is the rule in these cases. The dyspnœa is out of all proportion to the extent of lung involved in the tuberculous process. Some of the cases present an appearance strongly suggestive of Addison's disease. The physical signs of consolidation and excavation are usually imposed upon those of the fibrosis, but in some cases tubercle bacilli are found in the expectoration when the signs are those of simple fibrosis only. In the tuberculous group of cases there is usually a secondary anæmia, with reduction of corpuscles and hæmoglobin, and an increase in the leucocyte count up to 25,000 per cubic millimetre. As a result of his observations Dr. SUMMONS therefore divides the cases into two groups: firstly, simple, non-tuberculous fibrosis—in other words, a silicosis of the lung; and secondly, the mixed type, with a tuberculous infection in a fibroid lung. Of 204 cases positive evidence of tuberculosis was obtained in 95—that is, in 47 per cent.—but in several other cases there was a strong probability of their being of tuberculous nature, though actual proof was not forthcoming. In all fatal cases, however, tubercles were found and Dr. SUMMONS concludes that tuberculosis is the almost invariable cause of death in these cases. He records the results of the necropsy in 19 cases, of which ten are described in detail. The main changes induced by the sharp angular particles of silica appear to be peri-bronchial and interlobular pigmentation, chronic catarrh of the fine bronchioles, filling up of the alveoli with catarrhal products, subsequent fibrosis, and great increase of fibrous tissue around lymphatic and vascular channels. By the combining of areas of fibroid alveoli larger pigmented fibrous patches are produced in which no remains of alveolar wall can be recognised. When infection by the tubercle bacillus takes place caseation and cavitation occur, the process being somewhat modified by its incidence in fibrotic instead of normal lung tissue. The dust is first taken to the peri-bronchial lymphatic and thence to the bronchial glands; in sections of lung the dust particles are seen to be in lymphatic spaces, which are often blocked by them, and also in the subpleural lymphatics. Chemical analysis of the ash of the lungs of a Bendigo miner dying with a moderately advanced condition of silicosis gave 40·5 per cent. of silica, compared with 13·4, the amount found by HAMMARSTEN in the ash of normal lung tissue. The silica obtained in the ash proved on microscopical and chemical examination to be identical with the country rock of Bendigo, which is to be regarded as the sole exciting cause of the ordinary non-tuberculous "miner's phthisis," other factors, such as vitiation of the air and noxious fumes, being merely minor predisposing causes. To investigate the further implantation of tuberculosis in these cases Dr. SUMMONS measured the opsonic index in ten cases of non-tuberculous fibrosis and found it to vary between 0·7 and 1·16—i.e., practically within the normal limits of variation; in ten cases with superadded tuberculosis the index varied between 0·5 and 1·3. He infers that the great incidence of tuberculosis is caused by the diminished vitality of the damaged lung and not due to any general lowering of resisting power.

In regard to the prophylaxis and treatment some important corsets, with or without pads, have been devised in almost endless variety. Of these perhaps the best are two, one made by Salt and Co. of Birmingham, in which the pad is inflatable and is distended after the belt has been adjusted; the other made by Ernst of London, and recommended by Sir F. Treves. In some cases, no doubt, such appliances may be effective, but they are not always to be depended upon, and should they fail to support the kidney properly, should that organ indeed slip, as it is very prone to do, beneath them, so that pressure is brought to bear upon the kidney itself, they will greatly intensify, instead of relieving, the discomfort already felt. Moreover, some persons cannot bear the pressure necessary, or are so worried by the presence of the appliance that the nerve irritation persists and is increased. Morris says: "It is often stated that a well adapted belt is all that is requisite. I have not found it so; belts, pads, and trusses of all kinds are very unsatisfactory for this condition. They do not often effect any good, they must more often aggravate the suffering."

Sturmdorf says: "It is impossible to hold a prolapsed kidney in its normal position by any endurable pressure or tension exerted through the abdominal wall; not even the trained hand of the examiner can restrain a moveable kidney; coughing, sneezing, and muscular exertion will displace hand or pad and permit the kidney to fall into its abnormal position, where it will be firmly held by the compressing or constricting appliance, which thus defeats its own object."

I have not myself been able to succeed with these appliances; in one or two cases their use has at first been followed by good results but sooner or later the old troubles have returned and the belt has been discarded as useless. Still, it is not possible to consider all the testimony in their favour, from that of Sir Frederick Treves downwards, as mistaken, and the truth probably is that for some persons they are perfectly sufficient. Such cases should, I think, be encouraged to persevere with that mode of treatment; first, in almost all cases it would be wise to try its effect, and if it fails to have recourse to some form of operative interference. What form that interference should take we have now to consider, and it is in connexion with this part of the subject that I venture to suggest an alteration in the aim, and consequently in the technique, of the operation for nephropexy. In order to judge of the advisability of such alteration I will briefly emphasise the main points in the changes produced by this dislocation.

The kidney by its excursions has opened up for itself a cavity in the post-peritoneal connective tissue below and internal to its normal habitat; later, as the peduncle loosens and becomes lengthened, this cavity is still further enlarged downwards. Until this is closed there is always a potential cavity ready to receive the kidney should its restraining attachments give way. Whilst the superior extremity of the ligamentum suspensorium renis usually remains firmly attached to the diaphragm its lower extremity becomes opened out and lax. Any support which it may previously have given to the colon is lessened or taken away. The lower pole of the kidney becomes congested. Its pelvis is progressively dilated and contains more and more urine, which is never thoroughly emptied out of it. An operation, to be successful, must replace the viscus and hold it in such a position that both these results may be neutralised and completely prevented in future. As time goes on the ureteral attachment to the spinal column is gradually loosened, whilst the renal artery and veins become lengthened. An operation which would restore this attachment would have its advantages. Normally the posterior wall of the kidney is free and not adherent to the posterior abdominal wall. Its tissues contain no foreign substance on which sabulous material can collect and crystallise.

Up to the present time all operations for nephropexy have been made through an opening in the muscular wall posterior to the kidney, through which it is impossible to see whether or not the kidney is accurately replaced in its former location, and no attempt has been made to close the cavity in the post-peritoneal connective tissue below it.

It cannot be said that present methods have been uniformly successful. Many cases are on record in which the attachment made has again given way, and were this not so, the ever-increasing, ever-changing methods of posterior attachment would in themselves be evidence enough. Commencing with two or three sutures through the fatty capsule, operators have carried their ligatures deeper and deeper. At the fibrous capsule, indeed, a stand was made for a time; sutures were made to embrace more and more of this membrane; it was slit, turned back, and the raw internal surface united to the posterior abdominal wall. More and more sutures, up to ten double sutures (Lucas Championnière), or even 20 (Walsham), were used. Max Broedel introduced a very ingenious suture which, before it could tear out, must drag the capsule into the kidney itself.[4] Volliet utilised a strip of tendon from the erector spinæ and passed this beneath the capsule, anchoring it again below to the aponeurosis. But the stay here was short; other operators inclosed more and more of the kidney substance in the grip of their threads until Fenwick was able to describe an operation for renal calculus formed in the kidney pelvis around a suture which, introduced during a previous nephropexy, had penetrated that cavity.

No attempt has been made to supply inferior support to the kidney except, I believe, that once a sort of network of catgut was suggested which should hold the kidney as in a hammock. It is difficult to understand to what supporting posts the ends of the hammock were to be fastened; nothing further has been heard of this method, so I presume that it has been abandoned. In all cases the organ has simply been hung up to the posterior abdominal wall, so that in the upright position the weight of the organ is constantly exerting its force to loosen its attachments. Any suture which penetrates the kidney substance will have in its grip a certain amount of friable tissue, which is easily cut through, and the suture so becoming loose, the organ is no longer held firmly in contact with the surface to which it is intended to adhere. This adhesion is therefore never very firm even at first, and will become increasingly loose as the weight of the kidney comes to act upon it. Failure to secure a good result after operation was by some attributed to another cause: the fixation of the kidney at too low a level. I have already pointed out how difficult it always must be accurately to gauge the position of an organ seen only through an opening in the muscles behind it. Goelet says that "if the kidney is too low the operation does not facilitate its restoration to normal renal action; it does not prevent more or less constant renal congestion and accumulation of urine, owing to the flexure of the ureter which remains attached on a higher plane than the kidney."

The immense preponderance of right- over left-sided dislocation is not without significance. If, as I believe, the reason for this is the opposite action of the ascending and descending colon upon the renocolic band of either side it is evident that any operation which, as all posterior ones do, simply reproduces this pull has inherently a tendency to relapse. It would be a great advantage if this pull could be transferred to some other and more fixed point.

In the conception of any new operation for this condition attention should be paid to all these points and their full importance should be appreciated. It should supply the requisite support for the kidney, and that support, in order to be most effective, should be applied to the lower pole of the organ; it should close once more the opening to the post-peritoneal cavity formed by the kidney itself; it should enable the surgeon to replace the wandering kidney accurately in its original site, so that the vessels are not dragged upon nor the ureter kinked, and this replacement should be a matter of certainty, not of mere probability. It should give most support in the upright position, when it is most needed; it should not introduce into the secreting substance of the kidney any foreign material upon which calculi may form, nor should it depend upon tissues which, like the kidney, are friable, and will yield before the constriction produced by the sutures. If at the same time it can give a new *point d'appui* for the fibres which are continued into the posterior longitudinal band, and so take off the old drag upon the kidney, it will do much towards preventing any return of the dislocation.

The operation which I have devised, and which I submit to the judgment of the profession, aims at the satisfaction of all these indications, and also at the production of a Toldt's fascia, and the anchoring of the large intestine below the kidney in such a way as to produce on the right side the anatomical safeguards present normally on the left.

In old days, while yet the peritoneum was a sacred inclosure which must not be invaded except on the direst necessity, it was natural enough that an extraperitoneal organ should be attacked from without, however inconvenient the means of access, but at present and with our improved to the University of Cambridge, to the Educational Museum at Haslemere, to Brighton, and to Eton College and Windsor Castle. An exhibition of school building and furnishing appliances, which has been arranged by the Royal Sanitary Institute, will be held at the University of London during the week. It will illustrate the whole range of school hygiene both historically and according to every-day practice. For the convenience of delegates and members arrangements have been made with Messrs. Cook and Sons of Ludgate-circus, E.C., with regard to the provision of hotel accommodation. The capital of the British Empire having been chosen as the place of meeting for this congress it is eminently fitting that the buildings of the University of London should have been selected for the home of the Congress. Although South Kensington, where the university is now situated, is not quite so central as Burlington Gardens, Piccadilly, from which place it was removed a few years ago, still with the recent improvements in the means of intercommunication in London it is easily accessible from almost any part of the metropolis. Visited as the Congress will be by representatives from all civilised countries, by men of science and experts in educational methods, we look forward with hope to the results of its labours. We trust also that no bad impression will be left upon our foreign guests by any feeling that the Board of Education has not shown proper sympathy with the Congress. It must be explained to them that in this country no social or scientific movement ever waits for official sanction or support, because of the intimate knowledge that such assistance will probably be withheld, at any rate until the movement can do without the assistance. We are glad to see that the Education Committee of the London County Council has extended a general invitation to the Congress to visit all schools of the Council that are open during the session and has also appointed its chairman and vice-chairman, as well as the chairmen and vice chairmen of the special schools and day schools subcommittees, to represent it at the Congress.

THE MISUSE OF PRESCRIPTIONS.

A CORRESPONDENT has sent to us a specimen of a label issued by a dispensing druggist in Port Adelaide. The label sets forth that the contents of the bottle or packet to which it is attached are "The Original Dr. Jackson's Compound Sarsaparilla Blood Purifier and Reviver." Further, the label states that the nostrum is "Strongly recommended by the 'Lancet' and 'British Medical Journal.'" The label is a very good example of the way in which advertising druggists and quack medicine sellers contrive to give a little truth and to imply a great deal more than they have any right to do. It is not at all improbable that at some time or other some Dr. Jackson prescribed sarsaparilla, a drug which at one time had a great reputation as an "alterative." It forms the basis of most, if not all, of the so-called "blood-purifying" mixtures, and is generally made up with a certain proportion of potassium iodide. But to say that any particular preparation of this drug is "strongly recommended by THE LANCET" is an untruth. Unscrupulous persons to whom prescriptions are handed over, both dispensing druggists and patients, sometimes exploit a prescription for their own use. The dispenser makes a note of a prescription signed by some well-known medical man and in process of time, preferably after the death of the medical man, the dispenser issues the mixture, or whatever it may be, as "Dr. Diafoirus's celebrated mixture for ——. Prepared solely by ——." The condition for which the mixture is given will vary according to the fashionable complaint of the moment. With regard to patients we gave a striking example in our issue of Jan. 15th, 1898, p. 174. A patient had consulted a well-known specialist for wrinkles which had appeared on her face. He gave her a prescription which she handed on to many of her friends, after which she is reported as saying to the writer of the article in the lay paper from which we took the story, that she "thinks seriously of putting it on the market, so that it may have in the future a wider field of usefulness!" Another way in which prescriptions are misused is as follows. A patient is given a prescription for some complaint. He or she meets a friend who imagines that he or she is suffering from the same complaint. Patient No. 1 implores Patient No. 2 to try "the prescription that did me so much good." It is quite possible that No. 2 is suffering from quite a different complaint to that from which No. 1 suffered, in which case the prescription will certainly do no good and may very possibly do a great deal of harm. But the child-like faith in drugs and the ignorance of the general public about its health and the way in which its members will swallow anything, provided it be puffed enough, either in the columns of the daily press or by a friend, are astounding and would be ludicrous were the matter not so serious.

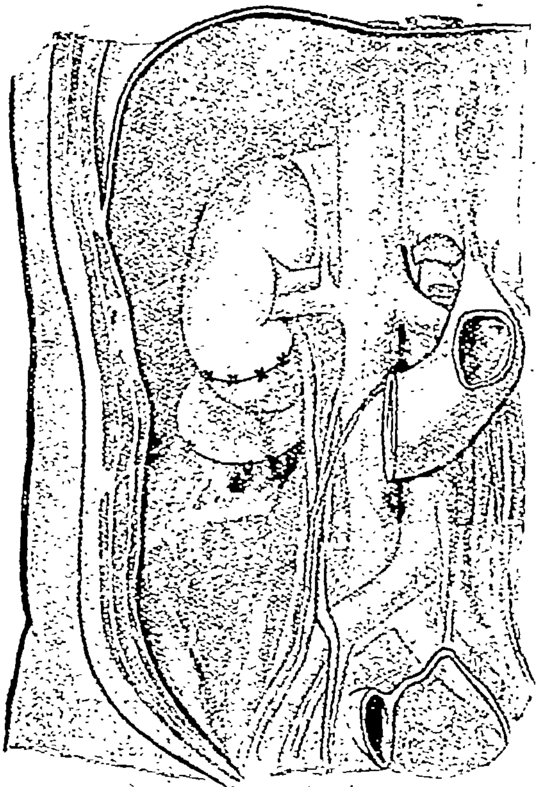
THE ACOUSTIC LIMITATIONS OF THE BINAURAL STETHOSCOPE.

THE *New York Medical Journal* of July 13th contains an important paper on the acoustic limitations of the binaural stethoscope by Professor Lewis A. Conner of Cornell University, who finds that for the perception of certain sounds, the naked ear has advantages over the stethoscope. A fact of interest in this connexion may be remembered. When the British physicians and surgeons visited Paris in 1905 our Special Commissioner was struck by the fact that the stethoscope had fallen into disuse even at the Hôpital Laennec and that auscultation was performed by applying the ear to a napkin placed upon the chest.[1] Only when exact localisation was desirable a stethoscope was used and this was a monaural wooden or metal one. The French physicians said that they could better appreciate the finer departures from the normal by immediate auscultation. Professor Conner has made a careful study of the sounds heard better by the naked ear than through the binaural stethoscope. He finds that the great majority of sounds arising in the heart are heard somewhat more distinctly through the stethoscope. But certain high-pitched whizzing or blowing diastolic murmurs may be clearly heard with the naked ear when inaudible through the stethoscope. The following is an example. A man, aged 51 years, had a good pulse with quick rise and fall and capillary pulsation on the forehead and lips. The first sound at the apex was somewhat impure, faint, and ill-defined; the second pulmonic sound was accentuated, and over the aortic area the sounds were fairly normal. With the stethoscope no murmurs were audible, but with the naked ear a faint, long, high-pitched diastolic murmur was heard over the sternum opposite the third rib and in the third left space. The patient was in hospital for weeks, during the whole of which time the peculiarity existed. Professor Conner has not been able to discover any other cardiac murmurs which fail to be transmitted through the stethoscope, but he thinks that some mitral or tricuspid regurgitant murmurs of the same blowing quality may not be transmitted. Thus the class of cardiac sounds better heard with the naked ear is small and of no great clinical importance. On the other hand, a large and important group of pulmonary sounds are best heard with the naked ear. This comprises a considerable proportion of all bronchial and amphoric breath sounds. Faint and high-pitched sounds be preferable, a curvilinear incision may first be made in the line which would be produced by the protruding points. If this is done it greatly facilitates the passage of the needles, and in my later operations I have always done this; in any case the penetrating sutures are tied and buried by a catgut suture through the skin and subcutaneous tissues. The closure of the abdominal wall in tier fashion completes the operation.

---

[1] THE LANCET, May 20th, 1905, p. 1356.

FIG. 3.



The lower flap of the kidney capsule is seen fastened to the fascia on the posterior abdominal wall by two sutures; the upper row of four sutures unites the cut edges of the peritoneum over the bared kidney tissue and the reflected capsule.

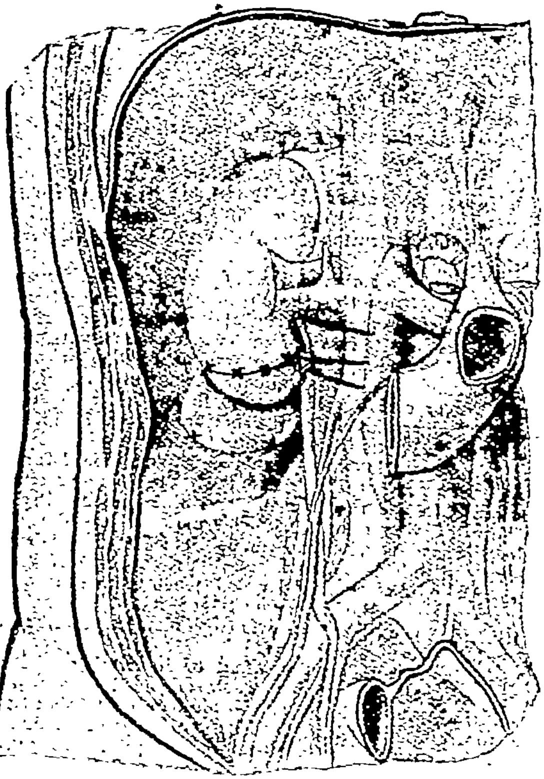
In the operation, as at first conceived, no attempt was made to utilise the fibrous capsule. The fixating loops were simply passed through the peritoneum, which was, therefore, not divided, and the subperitoneal tissues and muscles; but my friend and house surgeon, Mr. R. W. Porter, suggested this addition, and as it was evident that it would render the fixation more solid and complete I have adopted it in my later operations.

A careful consideration of the anatomy of the part, followed by demonstrations on the cadaver, show the following facts: 1. That there exists at the line which would be described by the lower edge of the kidney when in its normal position an area which is comparatively free from vessels and important nerves. 2 The ilio-inguinal and hypogastric nerves emerge at the level of the pedicle formed by the renal artery and veins and therefore lie above the line of the proposed suture. 3. The external cutaneous nerve lies altogether below the area involved. 4. The structures pierced by the needles are: the peritoneum, some fibres of the sympathetic system of nerves, the subperitoneal connective tissue, the psoas muscle, the anterior lamella of the lumbar fascia, the quadratus muscle, the posterior lamella, and some fibres of the latissimus dorsi. 5. Should the upper nerves be embraced by one of the sutures their position in the midst of the mass of the psoas muscle would protect them from injurious constriction, however tightly the sutures were drawn. 6 At the normal distance of the kidney from the spine the lumbar arteries entirely escape so long as care is taken to avoid the under surfaces of the transverse processes. 7. At this level a practically clear area exists in which there is nothing which can increase the ordinary risks of an operation.

After several trials upon the cadaver in order to prove the practicability of the operation I performed it first upon the living subject in February, 1906 Since then I have had nine other cases, or ten in all. The proceeding so far has had no mortality. It is, of course, too early to say anything as to the permanence of the results obtained; one of the earliest has relapsed, but in that one the capsule was not utilised, the needles being simply passed through the peritoneum. Experience of suturing intestine has shown that sutures quickly cut through this membrane, and apart from the advantage of a broader area of adhesion obtained by the reflexion of the proper capsule, it is evident that a much firmer and more permanent control is obtained over the kidney by including this membrane in the grip of the loops. In one case also the fixating threads, being of silk, suppurated, and had to be removed three months later, the kidney, however, remaining fixed. It has seemed to me that the constipation of which these patients had previously complained has been considerably improved. It is possibly to be expected that such improvement may be carried still further as the gut recovers itself under the new conditions.

Such an operation can evidently not be carried out if section of the kidney is required for any reason, such as renal calculus, pyonephrosis, or any similar complication. In such cases the extraperitoneal operation must be undertaken in spite of its disadvantages; nor is my method yet available for renal dislocation on the left side. As, however, in the great majority of instances the kidney recovers itself if maintained at the proper level and as the immense majority occur on the right side these disqualifications have not much weight. In most the anterior operation will be practicable and being founded on scientific reasons and being best fitted to meet the indications of this displacement will be found, I conceive, to give better and more permanent results.

FIG. 4.



The first stitch is shown with the needles *in situ* on the inner side of the kidney, immediately below the ureteric insertion. The thread is seen as it would lie after the passage of the needles and when drawn tight. The ends of the threads are of course much longer than shown, to allow of their passage through the muscular wall and their being tied behind. Of the second loop the upper thread has not been drawn through.

Manchester.

"liquid food" contains at least 100 calories, exclusive of alcohol and glycerine, it should not be depended on to sustain life even for a limited period. The council recommends that "liquid foods" should yield at least 8·8 per cent. of solids on evaporation and should possess at least as much nutritive value as milk. One-fourth of the nutritive value, exclusive of alcohol and glycerine, should reside in the nitrogenous matter. Further, the protein matter should be converted by enzymes—e.g., pepsin and pancreatin—and not by acids or by heat, as it is held by some observers that the products in the last-named cases may be toxic and dangerous.

THE STAFF OF THE JOHANNESBURG HOSPITAL.

WE learn from the *South African Medical Record* that the governing board of the Johannesburg Hospital has recently deprived the assistant staff of seats on the board. This has been accepted without opposition but another change that it has proposed is being vigorously opposed by the medical staff. This is that the board shall have power at any time to appoint outside practitioners directly to the senior medical and surgical posts of the hospital. It is claimed that this rule would not ordinarily be exercised but would be held in reserve for the case of some European celebrity who might happen to settle in Johannesburg and whose services should not be lost to the hospital because he was unwilling to pass through the usual period of the drudgery of out-patient work. Our sympathies are with the staff who are hostile to this change; it seems very unfair that those who have borne the burden and the heat of the day should be ousted from the clinical reward of their labours by the chance advent of a "European celebrity" who is unwilling to follow in their industrious footsteps.

RUPTURE OF AN AORTIC ANEURYSM IN A CHILD AGED THREE YEARS.

IN the *Journal of the American Medical Association* of July 6th, Dr. R. N. Willson and Dr. A. Marcy have reported the following remarkable case. A male child was born of apparently healthy parents five years after marriage, on Oct. 19th, 1903. The father admitted that he had twice had gonorrhœa but denied that he had ever had a sore on the genitals. But his nose was suggestive of the saddle type and at the age of 21 years he suffered from convulsive seizures resembling those of epilepsy. At the age of six weeks the child had bronchitis and while Dr. Marcy was examining the chest he heard a systolic murmur over the aortic cartilage which was so loud that it was audible over the whole chest, front and back. The circulation was good. On Nov. 17th, 1906, the child became ill with vomiting and rigors which recurred again and again. Malaria was suspected and quinine was given but without result. The rigors recurred irregularly and the temperature rose to about 102° F. and occasionally as high as 106°. The intervals were afebrile and then the child was bright and playful. But when the temperature rose he was dull and listless. At times he complained of distress in the epigastrium, occasionally in the upper chest. Sometimes he complained of pain in the neck; at other times the pain would shoot to his feet. He became anæmic and gradually weaker. On Dec. 13th Dr. Willson saw him in consultation with Dr. Marcy. The skin was sallow, almost of a lemon tint, and the mucous membranes were blanched. The cervical, submaxillary, axillary, epitrochlear, and inguinal glands were enlarged. In the episternal notch expansile pulsation was evident and a systolic thrill was felt, which extended over the whole upper chest. The upper part of the sternum and adjacent chest were absolutely dull on percussion. A loud, double, almost continuous murmur was heard with greatest intensity over the second right interspace and was transmitted over the entire præcordia and especially to the right scapular region. The abdomen (including the liver and spleen) seemed normal. Blood examination showed: red corpuscles, 2,000,000 per cubic millimetre; white corpuscles, 28,000 per cubic millimetre; and hæmoglobin, 40 per cent. The pallor deepened to a dusky hue, the face became puffy, and the left radial pulse almost disappeared. Congenital syphilis was diagnosed. A mass of enlarged bronchial glands, syphilitic or tuberculous, and congenital syphilitic endocarditis were suspected. Aneurysm was considered and but for the age would have been diagnosed. Death occurred on Dec. 26th. The necropsy showed an aneurysm of the ascending and transverse arch of the aorta which had ruptured into the pericardial cavity, advanced stenosis of the aortic orifice, and atheroma of the aorta. The liver was large and hard; the spleen was large but only congested. Dr. Willson and Dr. Marcy suggest that the aneurysm was of intra-uterine origin and due to syphilis.

THE ROYAL SOCIETY OF MEDICINE.

THE medical section of the Royal Society of Medicine is now fully constituted and is ready to receive papers for reading and discussion in the winter session. The section will hold its first meeting on Oct. 22nd, when Dr. Hector W. G. Mackenzie will open a discussion on the Complications and Sequelæ of Pneumonia and the Treatment of Pneumococcal Infections by Serum or Vaccine. The list of officials of the Royal Society of Medicine is as follows:—President: Sir William Selby Church. Honorary treasurers: Dr. F. H. Champneys and Mr. A. Pearce Gould. Honorary librarians: Mr. Rickman J. Godlee, Dr. H. Head, and Dr. Norman Moore. Honorary secretaries: Dr. Arthur C. Latham and Mr. H. S. Pendlebury. Members of council: Sir R. Douglas Powell, Mr. Henry Morris, Mr. J. Warrington Haward, Mr. G. H. Makins, Sir Shirley F. Murphy, Mr. T. L. Read, Sir Felix Semon, Dr. Frederick Taylor, and Dr. T. J. Walker, together with the presidents of the sections and the officers who are *ex-officio* members of the council.

A NOBLE FOUNDATION.

UNDER this heading the *Times of India* gives an interesting account of the Parsee Obstetric Hospital which was founded in Bombay about 20 ago by Dr. R. Temulji Nariman. Until this energetic and determined reformer led the way the treatment of Parsee women in their hour of travail was lamentable. They were isolated on the ground floor, usually in the most insanitary part of the building, and were attended by ignorant old women whose methods can only be described as barbarous. The infantile mortality in these circumstances was naturally very high; even now it is 11 per cent. outside the hospital, whereas inside, where the inmates enjoy all the advantages which the advance of Western science in the hygiene of obstetrics can place at their disposal, it is only 3 per cent. The institution is so highly valued by the Parsee community that the accommodation is always fully taxed. "We draw attention to these facts," says our contemporary, "not because there is anything new in them, the success of the hospital being familiar to the present generation, but because in these hurried days none should forget what lies behind them. This good work was not easily effected. There was a long battle against prejudice and custom in which, although he had the moral support of some leading members of the community, Dr. Temulji Nariman was always in the forefront. The hospital marks the bursting of the social fetters which were keeping the whole of the Parsee community in paralysing subjection; the advantages, direct and indirect, which it has conferred upon the race are

If the quantity of dextrose be lessened and a 1 per 1000 instead of a 3 per 1000 solution be taken, the following represents the nature of the result that is obtained. A much diminished formation of suboxide is, of course, involved in the alteration. With two cubic centimetres of Fehling's solution, two cubic centimetres of a 1 per 1000 dextrose solution, and two milligrammes of creatinine, a somewhat prolonged boiling is required to produce any change beyond a little fading of the blue colour of the test. The contents of the tube are then seen to become green and muddy, and afterwards yellowish-green, followed by greenish-yellow. In a repetition of this experiment, substituting ten milligrammes for the two milligrammes of creatinine, the fading of colour is seen to be more marked, and it is not till after very prolonged boiling that any further change is noticeable, when passage to green occurs, quickly followed by the assumption of a muddy green state and the subsequent acquirement of a greenish-yellow colour. During the boiling a copious evolution of ammonia takes place in the case of the experiment with the ten milligrammes of creatinine, whilst none may happen to be distinctly recognisable in the case of the other, although obviously it becomes developed.

The effect, then, of the presence of creatinine in connexion with the point under consideration is to more or less inhibit suboxide precipitation, the inhibition standing in proportion to the amount of creatinine present, and the phenomenon being attended with the evolution of ammonia.

MECHANISM OF THE ACTION OF CREATININE DISCUSSED.

Up to the present I have only given attention to the facts belonging to the subject under consideration and it has been seen that in the anomalous reaction what we have to deal with is: (1) an alteration of the character of the precipitate, which constitutes the most striking feature in connexion with the matter; (2) delay of precipitation, which when sufficiently prolonged may be attended with complete decolouration before precipitation occurs; and (3) associated evolution of ammonia.

In the second edition of my work, "Researches on the Nature and Treatment of Diabetes," p. 16, I referred to the modified reaction under consideration and ascribed it to the solvent influence on the copper suboxide of the ammonia liberated by the action of the alkali of the test on the ammoniacal compounds contained in the urine. I mentioned that ammonia was to be recognised escaping from the test-tube during the boiling, that no appearance of reaction might at first be noticeable, that after further boiling there might be a change to yellow or brownish-yellow without any deposit, and that on still further boiling and obtaining a more complete expulsion of ammonia the precipitation of suboxide might be observed to take place. This was the way in which I there expressed myself. Later, in my "Physiology of the Carbohydrates," p. 178, I stated: "Observation shows that an amount of sugar *distinctly* recognisable in a pure aqueous solution may not be *recognisable* when existing in urine. In water there is nothing to interfere with the deposition and consequently the *ready* perception of any suboxide that may be formed. In urine, on the other hand, the ammonia developed by the action of the potash of the test upon the nitrogenous matter present may suffice to hold in solution the suboxide produced when only small in amount."

Dr. Hugh MacLean has recently disputed the validity of this view. In Vol. I. of the *Biochemical Journal*, 1906, referred to at the commencement of this communication, he, in relation to the inhibiting effect of urine upon the sugar reaction with Fehling's test, asserts (p. 122) that "the chief factor concerned in this is kreatinin, and not ammonia as suggested by Pavy." He contends that the evolution of ammonia is of too insignificant a nature to produce the required effect, and at p. 114 makes use of the following argument: "Were the reaction due to ammonia present in loose combination, boiling the urine with the alkaline part of Fehling's solution for a comparatively short time *should be sufficient* [the italics are mine] to remove it; urines, however, to which small amounts of dextrose have been added previously, do not give any more indication of the presence of sugar after boiling than before." Farther on he says: "All this is contrary to the idea that ammonia is the substance that prevents small amounts of sugar from showing with Fehling's solution in normal urine; while it may have a certain effect in some cases it is ordinarily evolved in too small an amount to markedly interfere with the reaction."

Dr. MacLean surmises that boiling the urine with the alkaline part of Fehling's solution for a comparatively short time "should be sufficient" to remove the ammonia. If he had ascertained by observation the effect produced he could not have expressed himself as he has done. As a matter of fact, it is difficult to get away from the evolution of ammonia. Boiling may be carried on for ten minutes or a quarter of an hour and still ammonia is found to be freely escaping. The boiling even may be carried on in an open capsule until solidification has begun to take place, and then, on adding water and transferring to a test-tube, renewed boiling will be found to be attended with the free evolution of ammonia made manifest by moistened litmus paper introduced into the mouth of the tube.

After suggesting that boiling for a comparatively short time with the alkaline part of Fehling's solution should be sufficient to remove ammonia, Dr. MacLean follows with the assertion that urines to which small amounts of dextrose have been added do not give any more indication of the presence of sugar after boiling (to get free from the influence of ammonia) than before. Dr. MacLean seems to have overlooked the destructive action exerted by a fixed alkali on dextrose. Instead of there being more indication of the presence of sugar after boiling with the alkaline part of Fehling's solution, as is suggested should be the case through the expulsion of ammonia, the actual effect that occurs is a disappearance of the sugar. It is easy for anyone to boil some dextrose containing urine with the alkaline part of Fehling's solution, then add the copper portion and see the effect produced. Even with as much as 2 *per cent.* and over of dextrose present, and boiling only for one minute, sufficient destruction occurs to prevent any sign of reaction being obtainable, unless possibly it may happen after very prolonged ebullition that a slight show of precipitate may become apparent.

Since the above was written a second article has been published in the *Biochemical Journal* for April, 1907.[1] In this Dr. MacLean shows that he has discovered the facility with which dextrose is destroyed by the agency of a fixed alkali and that he has learnt the caution that is required to be exercised in experimenting with sugar in the presence of an alkali to escape arriving at a fallacious conclusion.

Looked at in relation to the view contended for, the points of inexactitude that have been referred to supply the main evidence upon which in the first paper the conclusion advanced was based, for there is nothing else that can be considered to afford any direct testimony in connexion with the matter.

Eury[2] advocated the view that creatinine is the source of the anomalous reaction under consideration and referred it to the formation of a soluble compound of cuprous oxide with creatinine. I have referred to Eury's article and find that he bases his conclusion upon the fact that the removal of creatinine from the urine by precipitation with the salts of mercury is attended with a loss of the inhibiting power over the production of the proper reaction that previously existed. He adduces no evidence touching the actual production and existence of the compound in question.

At this stage I thought it worth while to try experimentally if I could get the suboxide of copper taken up by creatinine. Measures were taken to obtain the suboxide in a finely divided form. 10 cubic centimetres of a 3 per 1000 solution of dextrose, 25 drops of Fehling's solution, and 15 drops of strong ammonia solution were boiled until the usual yellow precipitate appeared. This was obtained by centrifugalisation in a separated state and twice washed with water by the same process. Suspended in four cubic centimetres of water, a two cubic centimetre portion was boiled with 20 milligrammes of creatinine. Some of the precipitate evidently became dissolved but nothing settled out on cooling. Five drops of a strong solution of potash were added to the clear liquid to see if any manifestation of breaking-down effect was produced. No change of appearance occurred. Five more drops of potash solution were added and a translucent, colourless, flocculent precipitate settled out which disappeared on heating and reappeared on cooling. Nothing of a yellow suboxide character presented itself. Full boiling led, as might be expected, to the copious evolution of ammonia. Obtaining this result a search was made in chemical works to ascertain if any account was given of a combination between cuprous oxide and creatinine and it was found that Beilstein speaks under the head of creatinine of such a compound. In doing so he refers to the notwithstanding the handicap of a strange tongue Mr. Chettiar has produced a very fair *résumé*, so far as it goes, of modern learning in the matter of dysentery. His article is to be continued, so that further criticism had better be reserved. In addition to the journal of the All-India Hospital Assistants' Association we have also received another monthly publication entitled *The Hospital Assistant*, which has reached the sixth number of its second volume. The editor pathetically inquires, "What are our brethren doing in this matter? Out of thousands of hospital assistants in India how many are ready to spend a paltry sum of Rs. 2 for the sake of this journal, which is conducted in their own interests by a single individual?" Notwithstanding this lamentable state of affairs the little paper is decidedly meritorious, and doubtless deserves a more numerous *clientèle*. As the editor puts it, "Sincerity of work and uprightness of conduct must win in the end."

[1] Vol. ii., p. 169.

[2] Bulletin de la Societe Chimique, 1900, vol. xxiii., p. 41.

THE Nettleship medal, founded in 1902 to commemorate the work of Edward Nettleship and to encourage research in ophthalmology, was presented at the annual general meeting of the Ophthalmological Society to Mr. J. Herbert Parsons for his monograph on the "Pathology of the Eye."

Sir James Reid, Bart., M.D. Aberd., has been appointed a director of the Clerical, Medical, and General Life Assurance Society in the place of Sir John Williams, Bart., M.D Lond., who has resigned.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE sixty-sixth annual meeting of this association was held at the rooms of the Medical Society of London on July 25th and 26th, the early part of the meeting being under the presidency of Dr. ROBERT JONES who later inducted to the chair the new President, Dr. P W. MACDONALD, of the County Asylum, Dorchester.

The first morning was devoted to the internal business of the association. On reassembling the new PRESIDENT delivered his address which consisted principally of an examination of the social aspect of insanity in a purely rural district untouched by the influence of large communities. His inquiry extended over half a century of the history of the county of Dorset, during one-half of which time he had supervised the administration of the county asylum. In the "fifties" there were in the county scores of feeble-minded persons of all ages living free and simple existences in the villages unknown to Blue-book statistics and lunacy laws. But since the "seventies" the weak and defective persons had been gathered into the institutions of the country until the public had become alarmed at the cost of keeping these hordes of persons. 25 years ago the first admissions were in the ratio of 1 to 307 of the population; to-day the rate was 1 to 200. But in making the comparison it was essential to remember that since 1851 the birth rate of the county had fallen from 30 to 23 per 1000 and that migration had resulted in a net loss in that county of 82,000 persons. The types of insanity shown by first admissions exhibited no startling change, yet the change which did occur was significant of what had been happening in the county. In the agricultural boom of the "seventies" the percentage of mania among the admissions was as high as 65. In melancholia there was an advance from 18 per cent. in the "fifties" to 25 per cent. in the "nineties"; and the increase had been much more pronounced in the decades ending 1896 and 1906 than formerly, and in this he believed that intoxicating causes had played a conspicuous rôle, if only by rendering the individual hypersusceptible to every extraneous influence. But the really important point was the close association between the type of melancholia as met with in Dorset and the all-absorbing question of heredity. The dementias were not so easily dealt with, for ideas had changed and the whole aspect of things had altered in regard to the early dementias. He did not think the only reason for the high proportion of senile cases of dementia in rural communities was the lack of brain activity in those districts. The proportion in that type had risen from 5·8 per cent. in the "fifties" to 8·8 per cent. at the present time. That was not an alarming increase, but what about the residuum? He believed that it was due to causes other than lack of brain activity. The Poor-law authorities in the country districts failed to make provision within their walls for the aged mentally sick and by a process of devolution the Lord Chancellor, through the Lunacy Acts, ordained that those people should be gathered into homes. But in the early dementia a different condition of things was met with. The dementia præcox school ridiculed the homely terms "primary" or "early" dementia and some used "adolescent insanity" in preference to either. The question of primary dementia was full of interest in any attempt to study the phases of mental disease as exhibited by the admissions from the districts under consideration. In Dorset that class of case had advanced from 1 per cent. to 3 per cent. of the first admissions during the period under review That was an alarming increase of the most hopeless type of mental disease. Probably educational pressure, unhealthy environment, and passionate indulgence in various directions were important side issues, but the increase was really grafted on to an instability associated with the scourge of heredity. There had been an increase of 2 per cent. in general paralysis but it was not one of the common types in rural districts. The proportion of cases of epilepsy with congenital defect among the admissions had, however, risen from 4·7 per cent. to 8 per cent. during the fifty years, and that was one of the problems to be solved in any attempts to grapple with the question of race degeneracy. For the increase of these congenital cases the social life of depopulated villages was answerable. Summed up, it meant that melancholia, early dementia, and congenital defect—especially the last—had increased beyond comparison with any increase in the admissions, and the gravamen of those changes lay deeply buried in the social life of the people and help or relief must come from the root. In reference to the connexion between occupation and insanity he said that the increase had been in the group "no occupation," which had advanced from 6 per cent. to 12 per cent. His inquiry had established no clear connexion between certain occupations and special types of insanity. Still, there was an interesting state of things in reference to occupation and melancholia. The lack of interest and of direct stimulus to thought in large numbers of the peasant homes in Dorset had resulted in a state of gloom and despondency likely to be followed by melancholia, especially in people badly nourished. Whereas formerly the unmarried woman was engaged in laundry and dairy work, much of that was now carried on in factories and the simple peasant was therefore driven to eke out an existence in a variety of ways, many of which were not conducive to health. With regard to intemperance he included in that term far more than the abuse of alcohol, and suggested that the total abstinence school should greatly enlarge their list so as to include black tea and the pocket phial. He did not regard alcohol as even one of the greatest causes of insanity. Intemperance in alcohol could not be proved to account for more than from 3 per cent. to 5 per cent. of all cases of insanity in the county of Dorset; yet the Dorset peasant was as fond of his cider or ale as was the Lancashire miner. Dorset had one of the highest county rates in insanity, but one of the lowest in regard to alcohol as a factor. Dealing next with heredity, he said that in the sixtieth report of the English Lunacy Commission Dorsetshire was credited with the highest percentage of heredity as a factor in the production of insanity. His 50 years' inquiry led him to say that heredity was the main predisposing cause of insanity, and that the proportion of cases of hereditary origin had increased until it was now between 50 per cent. and 60 per cent. He concluded by urging the universal dissemination of a knowledge of those laws and facts which were the basis of personal well-being and expressing his high appreciation of the institutions for the insane in the United Kingdom.

Dr. G. H. SAVAGE proposed, and Dr. T. S. CLOUSTON seconded, a hearty vote of thanks to the President for his address, which was duly acknowledged.

Dr. C. C. EASTERBROOK (Ayr Asylum) read an elaborate contribution, illustrated by photographs, on the Sanatorium Treatment of Active Insanity by Rest in Bed in the Open Air. He discussed the advantages and disadvantages of the per 1000 solution of dextrose, one cubic centimetre of Fehling's solution, one milligramme of creatinine, and ten drops of the 1 in 10 solution of ammonia heated in the saline bath by the side of its counterpart containing ten drops of water in place of the ammonia, decolourisation was in each case noticed to occur to a like extent, and then after the lapse of some time signs of precipitation were perceived in the tube containing the ammonia 35 seconds before they became perceptible in the other. In a similarly conducted observation with 15 drops of the ammonia solution precipitation occurred simultaneously in the two tubes. With 20 drops of the ammonia solution a reversal of action was observed, precipitation occurring in the tube without the ammonia 55 seconds before it occurred in the tube with it. As regards the exact number of intervening seconds, there may be a slight variation noticeable in different observations, which may be possibly attributable to a slight variation of temperature of the saline bath, but the results always followed the same order. If a little paraffin is placed over the liquid in the test tube to prevent re-oxidation during the heating the results come out with greater sharpness.

By decreasing the amount of ammonia to one or two drops its effect is nullified. Increasing it from this stage up to a certain point is attended with an increasing neutralising effect on the action exerted by the creatinine. When the point in question is reached the further addition of ammonia operates in the opposite direction and adds to the effect produced by the creatinine.

Such are the facts connected with the phenomenon under consideration and I read their interpretation in this way. The creatinine inhibits coalescence and the greater the action occurring the longer the delay of precipitation and the finer the precipitate when it appears. Ammonia also inhibits coalescence and the effect naturally to be looked for from its conjoint action with creatinine should be, as in the case of association with albumin, an augmented result. Up to a certain limited point the reverse is what happens. A less effective inhibition occurs in the presence of ammonia up to the limited point referred to than in its absence, but when the point is passed the effect of the creatinine is added to by that of the ammonia. It seems therefore, in connexion with the phenomenon, as if the ammonia exerted an inhibiting influence on the inhibiting action of creatinine upon coalescence.

Leaving this matter, I will proceed a step deeper into the question and view it in relation to that of the mechanism of solvent action. By observation it is open to being seen by the eye that the inhibition of coalescence of the suboxide may be carried to the production of particles barely visible under the microscope. In this state the liquid is slightly opalescent and of a yellow tint. If the inhibition can be carried thus far, why may it *not* be susceptible of being carried further? If thus carried further, what, it may be asked, will constitute the condition presented? To this I would reply that there is nothing against its leading on to resultant solution, or to the production of a clear watery liquid containing the suboxide, perhaps in a free molecular, but at all events in an invisible, state.

In the case of ordinary solvent action we start with a something presenting itself in tangible form owing to its being under the influence of self-coalescence. When this something is placed in a solvent medium the solvent dissolves it and in doing so deprives it of visibility. The attraction power existing between the elementary constituents of the solvent medium and the substance particles is greater than that which previously held the latter together. As a result the substance particles are drawn asunder and incorporated with the solvent. But self-coalescence may again be made to occur. The issue depends upon which side the greater power exists. In the case of the suboxide of copper in relation to the question, if the normal self-coalescing or agglutinating power is allowed to have unimpeded play at the time of its formation it settles out in its characteristic normal form. If, on the other hand, the self-coalescing power is inhibited by an opposing power the issue occurring will depend on the relative strength of the respective opposing powers in operation.

I have spoken in a former part of this communication of two factors being concerned in the production of the anomalous reaction, one an influence interfering with coalescence of the newly formed suboxide and the *other* an agency for holding it in solution. They apply to the two kinds of physical condition observed. Under the proposition that has been just set forth these two factors merge into one, solution being representative of the final stage of the inhibition of coalescence.

(*To be concluded.*)

IODINE AS AN ANTIDOTE IN CARBOLIC ACID POISONING.

BY JOHN MABERLY, M.R.C.S. ENG., L.R.C.P. LOND.

DURING the last few years fatal cases of carbolic acid poisoning, both accidental and suicidal, have been steadily on the increase, due no doubt to the general knowledge and use of antiseptics. According to Allbutt, carbolic acid stands sixth on the list for frequency of fatal cases of poisoning, and there are probably few general practitioners of experience who have not been called upon at some time or other to attend cases. It is therefore very desirable that any possible improvement in treatment should be recorded, and it is on these grounds that I venture to bring before the profession a line of treatment entirely new but which is, so far as my experience goes, eminently satisfactory—viz., that of the administration of iodine in solution. I believe, in fact, that I have strong grounds for concluding that iodine is the true antidote for carbolic acid poisoning.

Up to the present the administration of solutions of the alkaline sulphates, originally introduced by Bauman and Heuter, appears as the most satisfactory line of treatment: the suggestion is that sulpho-carbolates are formed and the carbolic acid neutralised. Washing out the stomach with a soft rubber tube with solutions of alkaline or soluble sulphates or with pure glycerine as suggested by Whitla, and the administration of oils, egg albumin, and warm demulcent drinks are the recognised lines of treatment, of which, however, I have had no experience.

The first hint that I received as to the action of a solution of iodine on carbolic acid was from the late Mr. George Lawson at the Middlesex Hospital. In the then early days of antiseptic surgery the peculiar numbness and bleaching of the skin of the hands produced by saturating them in carbolic acid solutions was the common experience of all surgeons and hospital dressers, and it was when acting in the latter capacity that Mr. Lawson demonstrated to myself and fellow dressers the beneficial results produced by rinsing the hands so affected in a basin of warm water to which tincture of iodine had been added. The effect is almost immediately to remove the numbed feeling as well as the bleached crinkled condition of the skin; the iodine solution at the same time parts with some of its colour. It was this effect as an external antidote that induced me to try the effect of the drug internally on the first case of carbolic acid poisoning that came under my notice, and its beneficial action in that case encouraged me to carry out a similar line of treatment in the two other successful cases recorded below.

CASE 1.—One evening during 1895, in Bulawayo, a transport rider came in and requested me to go with him at once to attend a coloured "boy" at his wagon who had taken a draught from a bottle of crude carbolic acid in mistake for his master's whisky. Before saddling up I armed myself with a bottle of tincture of iodine, and on arriving at the wagon after a 20 *minutes'* ride found the patient sitting by the camp fire in great distress, frothing at the mouth, the lips, tongue, and fauces whitened from the effects of carbolic acid, his speech almost inaudible and his breathing difficult on account of the condition of the larynx; he was endeavouring to drink a cup of milk, but was, however, unable to swallow it. I poured about a small teaspoonful of tincture of iodine into a cup of water and told the patient to drink it slowly. This he did without the slightest difficulty and rapidly began to feel easier. Shortly afterwards he drank the milk, which previously he had been unable to swallow, his voice and breathing improved, and the symptoms of distress gradually disappeared. Before leaving I gave him some more solution of tincture of iodine with instructions to drink it slowly at intervals during the night. The next morning the transport rider came in and told me that the patient was quite comfortable, and that afternoon he was able to continue the journey with his master, consequently I saw nothing further of him.

CASE 2.—The patient was a child, living in Woodstock, Cape Colony, aged three years, who had drunk some Jeyes' reception of bed-pans the contents of which await inspection. The operating room skylight is provided externally with a large plate-glass shield, the open air-space between being fitted with a steam coil to prevent cold air falling on the operating table; it also protects the skylight from condensation and snow. The windows are of special construction so as to obviate draught and the accumulation of dirt. The subjects of ventilation, protection against fire, and the sanitary appliances have received great attention from the architect and are deserving of more extended notice.

Ventilation.—140 feet of floor space per bed have been provided, with an allowance of 2000 cubic feet air space, six beds being placed in each ward. This is a liberal allowance when compared with some general hospitals, but here each bed is accompanied by a cot, so that the allowance to the patient is somewhat reduced, while the presence of students renders the 140 feet of floor space desirable. Four of the wards are ventilated by means of electric motors, working four especially powerful fans in connexion with a system of metal flues. A separate flue is connected with each ward at the ceiling level and regulated to extract 36,000 cubic feet of air per hour (though capable of extracting a much larger quantity), thus changing the air of each ward three times every hour. There being six beds in each ward mother and child have an allowance of 6000 cubic feet of air per hour from this source alone, while in addition to this there is the cross ventilation from the windows. The air flues are fitted with inspection chambers for the collection and removal of any dust. In the four remaining wards the air is extracted by a different process; certain specially constructed glazed 12-inch flues are carried up in the thickness of the wall terminating in short turrets, which last are formed to create an upward current in the flues, independently of the direction of the wind. Into each of these flues a smaller one is carried from the ward to be ventilated, bending upwards a short way into the larger one, where a vacuum can be created by means of a jet of steam admitted in the lower part. It has been found possible to change the air of these wards within ten minutes. The labour wards are ventilated by means of the furnace shaft of the boilers. All ventilating shafts are distinct one from the other. Only in the isolation wards situated on the roof, is natural cross ventilation relied upon, augmented by short flues carried up from the ceiling, fitted with talc louvres to counteract any down draught. In every ward fresh air is admitted at four points through external gratings at the floor level; here it is filtered through worsted screens. The use of worsted threads was suggested by the hairs present in the nose, which forms nature's air filter. The incoming air is heated as may be necessary by passing through a steam-jacketed coil, where by a simple contrivance of covered channels and baffle plates the air can be deflected at varying temperatures to deliver under each bed and distributed generally. The whole system is well under control, while every part, coils included, is accessible for cleaning. A system of telephones communicates with the boiler house from each ward, where means of regulating heat and ventilation are under the control of the engineer.

Fire.—The building is of the usual fire-proof construction, the use of all inflammable material being reduced to a minimum, the floors being of a new cement composition and jointless. They are impervious to wet and are capable of receiving considerable polish, are soft to the tread and fairly warm, resembling asphalte, while the red colour adds a look of comfort to the wards. It would seem an ideal material for the purpose, but time is required to prove if it fulfils its promise. The whole of the roof is accessible from two iron external staircases and is connected throughout by guarded causeways. Teak doors of ample size lead to the staircases from each corridor and are fitted to open from the inside with push-bar latches and externally by a master key. These staircases not only offer a ready means of escape in the event of a fire but of access to any part of the building for the engineer or workmen without having to pass into any other part than the one desired, not an inconsiderable advantage. There is a complete system of hydrants, each one of which is, sealed by the Metropolitan Water Board which imposes a charge of 20*s.* for the fracture of any seal, and this seriously militates against the efficiency of the hospital fire staff and the security of the inmates. A less charge should suffice to permit the occasional testing of the hydrants and to accustom the staff to their use.

Sanitary work.—This has evidently been planned and executed with thought and care. New departures principally consist of the following:—The sinks. These are fixed away from the walls and are almost oval in shape; every portion inside and out is rounded and accessible for cleaning. They are made of exceptionally good white glazed porcelain. The floors being impervious there are no overflows, neither are there any traps to the sink wastes, which are short, discharging into white glazed open channels let into the floor, and these discharge externally. The gun-metal valves are operated by the foot, the elbow, or the knee on the pattern of Messrs. Davis and Bennett who are responsible for the plumbers' work. In the isolation ward the pipes are independent of those in other parts of the building. The infants' washing wards are specially warmed and are fitted with a double row of small white porcelain baths down the centre. They have the same finish as the sinks and are fixed some 2 feet 3 inches from the floor. Each pair of baths is supplied with hot and cold water by a rotating crane douche. The nurse sits at the bath having both hands free, the valves being controlled by a pedal and the waste by a knee lever. The labour wards are fitted with two similar baths for hot and cold water for use in cases of suspended animation occurring at birth. The pipes passing through these wards are fitted externally with a very ingenious air-trap charged with glycerine preventing air from passing along outside the pipe from ward to ward. The closets, baths, lavatories, and ward sinks are all of the most approved design.

Water-supply.—A store-room on the roof contains two large iron tanks connected together to hold two days' supply, which is constant from the main. The down services are drawn from the tank at the farthest point from the inlet to insure circulation, but in the event of repairs the service can be diverted and drawn from either tank or both tanks can be shut off and the rising main and down services short-circuited. The waste-preventing cisterns supplying the closets, &c., are almost devoid of accessories. They are fixed clear of the wall by two long iron lugs cast on the cistern, which lugs are built into the wall in place of brackets, and the whole finished in white porcelain enamel. The drains have no special feature of interest. They are of heavy cast iron and automatically flushed from their upper end, thoroughly ventilated, and disconnected. Every soil pipe is fitted with brass inspection eyes at each branch or bend and some special copper draught excluders fixed on the overflow pipes supersede the usual flap valve.

The architect, the builders, and others concerned have produced a building which is admirably adapted for the purpose intended. It remains for the management to see that the several provisions are rightly understood and properly maintained. Especially is this the case with the ventilation and fire appliances, it being important that the air-flues and screens should be kept clean and the air-traps charged with glycerine. The swing coils also should be frequently moved. Fire drill should be maintained and dummy patients carried down the external staircases and beds run from the wards to the nearest landing as would be necessary in the event of a fire.

To celebrate the completion of his work the architect promised a donation to the first child born within it. The mother, however, was more than equal to the occasion and brought forth twins!

EPSOM COLLEGE.

FOUNDER'S day was commemorated at Epsom College on Saturday, July 27th, special importance being attached to the function this year in consequence of the dedication of a handsome jubilee memorial window in the College chapel. The attendance of parents of boys and of friends of the College was very large and it was gratifying to note that there were many old Epsomians amongst the visitors, several of whom entered at the opening of the school in 1855. The Dean of Winchester dedicated the window and gave away the chief prizes, and amongst those present were Sir William S. Church (chairman of the council), Mr. Henry Morris (President of the Royal College of Surgeons of England), Mr. Stanley Boyd, Dr. Clement Godson, Dr. F. de Havilland Hall, Mr. Reginald Harrison, Mr. W. F. Haslam, Sir Constantine Holman, Mr. H. W. Kiallmark, Dr. F. Needham, Mr. Frederick Propert (the only surviving son of the founder, who gave away the "Propert" prize), Dr. Guthrie Rankin, kidneys were slightly adherent and the cortex was moderately enlarged. The intestines showed nothing abnormal; a few round worms were found in the small intestine. The uterus was atrophied and bound down by dense peritoneal adhesions. The vagina showed evidence of chronic inflammation of its mucous membrane and presented patches of pigmentation similar in character to those present in the mouth. On the vulva were a few small leucodermic areas. Both suprarenals were enlarged and exhibited caseous masses in their substance apparently affecting the cortex. Their capsules were much thickened and adherent to the surrounding parts. These bodies and portions of pigmented mucous membrane and skin were submitted for microscopic examination to Dr. J. R. Dickson, the pathologist to the hospital, who reported as follows:—"A. Suprarenals: (1) normal suprarenal tissue towards the medulla; and (2) caseating masses, at the margin of which were giant cells, in the cortex. The condition was tubercular with marked tendency to caseation. B. Skin and mucous membrane: showed marked pigmentation of the basal cylindrical cells. Below this layer in the cutis were scattered branching pigmented cells, which appeared to be invading the epidermis." The fibro-caseous changes in the suprarenals in association with the clinical features of the case seem to leave no doubt as to the correctness of the diagnosis.

As far as I know, only one case of this disease has been reported in this colony. The notes of the case were recorded by Dr. Beaven Rake in THE LANCET[1] and also in his annual report on the Trinidad Leper Asylum for the year 1889.

Trinidad.

NOTE ON A CASE OF TUBERCULOUS CEREBRO-SPINAL MENINGITIS.

BY STANLEY HODGSON, M.D., B.S. LOND.,
M.R.C.S. ENG., L.R.C.P. LOND.,
HONORARY PHYSICIAN TO THE PENDLETON BRANCH OF THE SALFORD ROYAL HOSPITAL.

THE interest in the following case lies chiefly in the anomalous symptoms and course of the disease.

The patient, a girl, aged three years, was said to have been entirely free from the usual childish complaints. She was bright and rather precocious. Her parents were both healthy and she had a good family history so far as I could ascertain it. I first saw her on July 4th. She had been ailing then, according to her mother, for about a fortnight. The illness was an indefinite "out-of-sorts," and at the hospital where the child had been taken the opinion had been given after a careful examination that nothing was the matter. Certainly, on July 4th, the only evidence of illness was a temperature of 100° F. and some constipation. During that night the child screamed with abdominal pain, which was relieved by hot applications and the exhibition of castor-oil.

A careful examination of the abdomen and thorax revealed nothing abnormal. The next day the condition was the same. The child was a little irritable and cried out if touched. She would lie contentedly if nursed by the mother. In the evening another attack of abdominal pain occurred which was again relieved by the hot poultice and castor-oil. On the next day the child seemed a little better and was not so fretful. She took milk well but was apathetic and did not speak. Tache cérébrale was present and the left knee-jerk was somewhat exaggerated. The left arm was frequently thrown above the head. The pulse was 90 and the temperature was 100°. On the 7th the child was drowsy but was free from all pain. The friends thought that she was much better as she had passed a good night. Her temperature and pulse did not vary. The difference in the knee-jerks was still noticeable and in addition there was slight but definite resistance on extending the leg with the thigh semi-flexed (Kernig). The pupils were about three millimetres in diameter. On the next day the child became unable to swallow—that is to say, the presence of milk in the mouth did not evoke the swallowing reflex. Two hours after this was noticed, at about noon, she had a fit in which there was marked opisthotonos and movements of the arms and legs simulating tetany. The duration of the fit was not more than 30 seconds and the convulsive movements continued every hour, diminishing in force until they ceased on the 10th. There was no rigidity of the neck muscles. This sign was first seen on the 9th and was very slight. The breathing, too, assumed a Cheyne-Stokes character with a very short period. The pulse was of good volume, regular, and 100 per minute. The temperature in the evening rose to 102°. The general aspect of the child was that of a healthy baby quietly asleep. On the 10th the condition was much the same with these exceptions. The knee-jerk was absent on the left side and very faint on the right. The pupils were fixed at three millimetres and did not react to light even when illuminated by the ophthalmoscope. The temperature was 104° in the morning and 105° at night. The bowels were kept open by enemata and the child was given nutrient injections which were not retained for more than an hour. Perspiration was very profuse and micturition scanty. Retraction of the head was evident, Kernig's sign was well marked, and coma was complete. The breathing now resumed its normal character with a frequency of 40. The pulse-rate steadily increased. On the 11th, with Dr. J. J. Butterworth, the assistant medical officer of health of Salford, lumbar puncture was performed and a non-purulent, blood-stained fluid was drawn off and reserved for bacteriological examination. Dr. Butterworth also examined the discs which presented nothing unusual. On that night the temperature (axilla) reached 107° and the pulse 170, and at 1.30 A.M. on the 12th the child died. The bacteriological report was as follows: "A portion of the fluid was centrifugalised and search was made for the diplococcus intracellularis but none was found. Films stained Ziehl Neelsen showed the presence of tubercle bacilli in extremely small numbers."

No post-mortem examination was allowed. There was no obvious tuberculous focus, though the preceding abdominal condition, and the fact that the child had a habit of picking up and eating rubbish from the streets, point somewhat to the abdomen as a prime source.

Salford.

Reviews and Notices of Books.

Indications for Operation in Disease of the Internal Organs. By Professor HERMANN SCHLESINGER, M.D., Extraordinary Professor of Medicine in the University of Vienna. Authorised English translation by KEITH W. MONSARRAT, M.B. Edin., F.R.C.S. Edin., Surgeon to the Northern Hospital, Liverpool. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co. 1906. Pp. 498. Price 9*s.* 6*d.* net.

WITH the many advances made in operative procedures and in surgical technique not a few diseases and morbid conditions formerly entirely within the province of the physician have within recent years come more and more into the surgeon's hands for operative treatment directed towards radical cure of the condition, where that is practicable, or for palliative measures, or as a last resort where medicinal treatment has failed. There has thus arisen a common ground in regard to these conditions, a jointly occupied territory as it were, in connexion with which problems may arise requiring great care, judgment, and experience for their decision in respect of the choice of medical or surgical treatment, necessitating an experience, too, of the results of both. In Germany the importance of these considerations has been recognised by the establishment of a journal devoted to the discussion of matters affecting the boundary regions between medicine and surgery. In this country, although the importance of this subject is recognised, the literature is very scattered.

Professor Hermann Schlesinger of Vienna has published his book primarily as a guide to the general practitioner in determining the advisability or otherwise of surgical intervention. In his preface he suggests that there should be some advantage in a discussion of the question of surgical intervention in cases of medical character by a physician who is in full sympathy with the standpoint of the surgeon. In this view we concur and Professor Schlesinger's book is of considerable value from this very fact. A further

[1] THE LANCET, August 3rd, 1889, p. 214.

1909 were then announced: *Dr. H. S. French to deliver* the Goulstonian lectures, Sir James Sawyer the Lumleian lectures, Dr. Pye-Smith the FitzPatrick lectures, Professor E. A. *Schäfer the Oliver* Sharpey lectures, and Mr. L. S. Dudgeon the Horace Dobell lectures for 1908, and Dr. W. S. Lazarus-Barlow the Croonian lectures for 1909.

Arthur Shadwell, M.A., M.D. Oxon., and Thomas Macrae, M.D. Toronto, who were elected to the *Fellowship on* April 25th, were admitted as Fellows of the College.

The following gentlemen having passed the required examination were admitted as Members of the College: Arthur Wellesley Falconer, M.D. Aberd.; Vincent Sutherland Hodson, M.B. Oxon.; Bernard Hudson, M.A., M.B. Cantab., L.R.C.P.; Harold Charles Corry Mann, M.D. *Lond.*, L.R.C.P.; Reginald Henry Miller, M.D. Lond., L.R.C.P.; Harold Pritchard, M.D. Lond., L.R.C.P.; Ernest Athole Ross, M.D. Cantab.; George MacIver Campbell Smith, M.A., M.B. Aberd.; Frank Edward Tylecote, M.D. Vict.; and Samuel Alexander Kinnier Wilson, M.A., M.B. Edin.

Licences to practise physic were granted to 114 gentlemen who had conformed to the by-laws and regulations and passed the required examinations.

Diplomas in *Public Health* were granted to 13 successful candidates.

Communications were received from:—

1. The *London* County Council thanking the College for the report of a committee convened to discuss the notification of cases of posterior basic meningitis and cerebro-spinal fever and inclosing certain recommendations made by the Public Health Committee of the *London County Council* as a result of that report.

2. The committee of the International Congress on *Psychiatry, Neurology, &c., to be held in Amsterdam* from Sept. 2nd to 7th next, *inviting the College* to send delegates.

3. Sir Dyce Duckworth, representative of the College at the funeral *of* Sir Joseph Fayrer.

4. Dr. G. A. Heron, representative of the College at the funeral of Dr. Robert Barnes.

These were received and ordered to be entered on the minutes.

5. Dr. James Ramsay of York, offering to the College an autotype copy of a portrait *of* James Atkinson, 1759–1839, author of Medical Bibliography, letters A—B. It was directed that the thanks of the College should be given to Dr. Ramsay for his gift.

6. The Registrar of the General Medical Council, communicating the revised recommendations of the Council with regard to the instruction of students in practical midwifery. This *was* received, entered on the minutes, and referred to the Committee of Management.

7. The secretary of the *Royal* College of Surgeons of England (3) *reporting proceedings* of its Council on May 9th, June 13th, and July 11th. These were received and entered on the minutes.

The following Censors, other College officers, and examiners were elected on the nomination of the President and Council:—Censors: Dr. David Ferrier, Dr. John Mitchell Bruce, Dr. *Thomas* Clifford Allbutt, and Dr. James Frederick Goodhart. Treasurer: Sir Dyce Duckworth. Emeritus registrar: Sir Henry Alfred Pitman. *Registrar*: Dr. Edward Liveing. Harveian librarian: Dr. Joseph Frank Payne. Assistant registrar: Dr. *Oswald* Auchinleck Browne. Elected members of the library committee: Dr. *Norman* Moore, Dr. William Osler, Dr. Humphry Davy Rolleston, and Dr. Charles Arthur Mercier. Curators of the museum: Dr. William Cayley, Dr. *William Henry* Allchin, Dr. Seymour John Sharkey, and Dr. William Hunter. Finance committee: Dr. *David Bridge Lees*, Dr. Francis Henry Champneys, and Sir Edwin *Cooper Perry*. Examiners: *Chemistry*—Mr. John Millar Thomson, F.R.S., and Mr. George Senter, Ph.D., B.Sc. Physics—Dr. Dawson F. D. Turner and Mr. Alfred W. Porter, B.Sc. *Materia* Medica *and Pharmacy*—Dr. Cyril Ogle, Dr. Joseph John Perkins, Dr. Robert Arthur Young, Dr. James Purves Stewart, and Dr. Otto Fritz Frankau *Grünbaum*. Physiology—Dr. William Dobinson Halliburton and Dr. Ernest Henry Starling. Anatomy—Dr. Peter Thompson. Medical Anatomy and Principles and *Practice of Medicine*—Dr. Joseph Arderne Ormerod, Dr. Sidney *Harris Cox* Martin, Dr. William Collier, Dr. Hubert Montague Murray, Dr. Norman Dalton, Dr. Humphry Davy *Rolleston*, Sir Edwin Cooper *Perry*, Dr. Frederick John Smith, Dr. Arthur Pearson Luff, and Dr. Walter Essex Wynter. Midwifery and Diseases Peculiar to Women—*Dr. John* Phillips, Dr. Herbert Ritchie Spencer, Dr. William John *Gow, Dr.* Thomas Watts *Eden, and Dr. George H. Drummond* Robinson. Public Health—*Part I., Dr. William Henry* Willcox; Part II., Mr. Alexander Grant Russell Foulerton. Murchison Scholarship—*Dr. Seymour* John Sharkey and Dr. William Hale White.

The Baly medal was awarded to Dr. Ernest H. Starling, F.R.S., *Jodrell* professor of physiology, University College, *London*, as having pre-eminently distinguished himself in the *science* of physiology.

A report was received *from* the representative of the College *on the General* Medical Council on the proceedings of the Council during its session in May last. This was adopted and directed to be entered on the minutes.

On the motion of the Registrar, seconded by the Senior Censor, the following *by-law was enacted for the first time*, viz.:—

> That Daniel Colquhoun, M.D. Lond., and George Edward Rennie, *M.D. Lond., elected Fellows on April 25th, residing* in New Zealand *and Australia* respectively, be admitted *in absentiâ*, any by-law to the contrary notwithstanding.

The Registrar moved for the first time that alterations be made in certain by-laws *relating to Licentiates to make* them conformable to the revised regulations of the Conjoint Board, adopted on April 25th last. This was seconded by the Senior Censor and carried.

On the recommendation of the committee of management Dr. H. H. Tooth and Mr. A. G. R. *Foulerton were appointed* assessors to the examinations of the London School of Tropical Medicine for the year ending June, 1908, and the following institutions which had been visited by a member of the committee and reported as fulfilling the requirements of the board were added to the list of institutions recognised by the *examining board* in England for instruction in chemistry and physics: *Municipal* Technical School, Birmingham; Alleyn's School, Dulwich; and Aldenham School, Elstree.

The quarterly report of the College finance committee, the annual report of the library committee, and the annual report of the *curators of the museum* were received and adopted.

A list of books and other publications presented to the library during *the past quarter was* submitted and the thanks of the College were directed *to* be conveyed to the donors.

The *quarterly report* of the *examiners for* the Licence on the results of the examinations in April last was received and adopted.

The President then dissolved the Comitia.

BRITISH MEDICAL BENEVOLENT FUND.

At the July meeting of the *committee* reference was *made by* the chairman to the recent death of Sir William H. *Broadbent*, the President, and a resolution was passed to express the committee's deep regret and sympathy *and to* record its *sense* of the invaluable services rendered by him to the Fund. The banking account was reported to show a deficit and it was therefore necessary, having regard *to* the urgent nature of the applications, to draw upon a small reserve fund created after the last special appeal. *No* less than *32* cases were considered and grants *amounting to £256* were voted in relief, one applicant only being passed over. The sums given were in most instances smaller *than* usual and much disappointment has consequently been caused. Appended is an abstract of the cases assisted:—

Daughter, aged 62 years, of late *M.D.* St. And., who practised in Devonshire. *Only income* an annuity of £11 and has been *obliged* through ill-health to give up post as companion. Voted £12.

Widow, aged 71 years, of M.R.C.S. *Eng.*, *L.R.C.P. Edin.*, who practised in *Lancashire*. *Is at present* penniless, but has a chance of receiving an allowance *if* certain unavoidable expenses can be met. Voted £20.

Daughter, aged 66 years, of *late M.R.C.S.*, L.S.A., who practised in Wales. Has a small annuity and a little help from relatives, but means are insufficient to bear the unavoidable expenses of moving from unsuitable lodgings. Voted £2.

Widow, aged 61 years, *of M.D. Edin., who practised* in Liverpool. No income; a small weekly allowance received *from* a *Lancashire* benevolent institution will shortly *cease*. *Health delicate.* Two children, unable to help. Voted £12.

Widow, aged 60 years, *of* M.B., *C.M. Aberd.*, who practised in Fifeshire and has recently died from pulmonary tuberculosis after a *long* illness. Expects *to have an income of about* £20 a year and proposes to take boarders. Three children, the *eldest* 13. Voted £12.

Widow, aged 37 years, *of* M.B., C.M. Aberd., who *practised* in Pembrokeshire. Quite unprovided for at recent *death of* husband. Slight submitted, if possible, to unirritating restrictions calculated to save the easily tempted from a fall. Herein lies the whole difficulty. If all men were equally endowed in regard to their power of resisting evil and realised where use ceased and abuse began and acted accordingly the question of legislative control would hardly concern us. One thing is certain, however; the human being will never be made a total abstainer by Act of Parliament. On the other hand, any movement that seeks to disseminate the spirit of temperance will do far more to secure the "godly, righteous, and sober life" than the putting forward of extreme propaganda.

We believe with Mr. Pratt that nobody better than the trade itself recognises this and it is gratifying to learn that at least a large section of the trade desires to see a temperate people as much as does any well-intentioned reformer. It was not more than a score or so years ago when it is to be feared the only idea of most merchants was to sell as much alcoholic liquor—good, bad, or indifferent—as they could to accumulate profits rapidly without any regard to the moral effects on the consumer. "My business," a dealer would say, "is to sell and not to lay down what is, or what is not, good for my customer." All the public need ask at the hands of the trade is that it should be honestly dealt with. Recent years have witnessed fresh attempts to supply *some substitute to the* consumer instead of the genuine article. We are told, for example, that invert sugar is as good as malt and makes a lighter and more palatable beer. Then why not tell the public so if it appreciates the change? Mr. Pratt defends the use of beer of light alcoholic strength which he says only the introduction of modern methods involving the use, *inter alia*, of invert sugar has enabled the trade to supply. On the other hand, he says in another place that our forefathers "bequeathed us not only *bodies that are* none the worse, physically, because they themselves loved strong ale, but a freedom which we shall either curtail or abuse if we say that because a small *proportion of the* community suffer from the effects of an undue *consumption of* alcoholic drinks, therefore the rest of the nation shall be compelled to abstain therefrom." Now *our forefathers* drank beer which answered to the simple *formula of* malt, yeast, hops, and water, while their *descendants* are told that malt substitutes are *better for them.* We know, of course, that some years ago the use of malt substitutes cost the nation a serious *epidemic of* arsenical poisoning and not a few lives. We are *told again* that whisky is better for the consumer if it is not made from barley malt and that it is immaterial whether brandy be distilled from wine or other materials, *when it is patent to* everybody that the introduction of substitutes simply means, as a rule, a cheaper product and a wider margin of profit.

We think that Mr. Pratt's attack on temperance drinks in Chapter XVI. is a tactical blunder. The manufacturer of temperance drinks, such as soda water, ginger-beer, and lemonade, like the brewer, the distiller, and the wine-grower, has his temptations, but we venture to say that in this country, at any rate, the supply of non-alcoholic beverages is, on the whole, very satisfactory. As to the fact that some temperance beverages contain a little alcohol which is generally much less than 1 per cent. by weight we scarcely think that they can be regarded as in any sense intoxicating. Mr. Pratt also quotes medical authorities on the injury to health that may arise from the drinking of tea and coffee. This is all a feeble *tu quoque* and serves no good purpose. The question of abuse applies just as much to so-called temperance beverages as it does to alcoholic liquors. We should like to know Mr. Pratt's authority for stating the following on p. 238: "*Just as in the human system Nature manufactures sufficient alcohol to preserve from acidity the food taken into the stomach* (and to this cause is due the fact that abstainers seem to demand, or are more partial to, sugar and sweets than are people who drink) so in like manner Nature produces her own alcohol in the product called beer to act as a preservative." The words in italics (which are ours) surely express a complete physiological chimera.

We must admit, however, with these exceptions that Mr. Pratt has presented a very fair and temperate view of the question. With much he has written we entirely agree. He deplores drunkenness, so do we; he advocates honest dealing, so do we; he enjoins an unprejudiced view of the situation, so do we; and he appeals against the introduction of any ill-considered legislation which is likely to smash a great industry which moreover contributes greatly to the revenue of the country, so also do we as long as that industry conducts its business on lines which promote temperance and which protect its *clientèle* against sophistication and fraud.

Marriage and Disease, being an abridged edition of *Health and Disease in Relation to Marriage and the Married State.* Edited by Professor H. SENATOR and Dr. S. KAMINER. Translated from the German by J. DULBERG, M.D. Würzburg. London: Rebman, Limited. 1907. Pp. 452. Price 10*s.* 6*d.* net.

THE progress of sociological investigation in modern times has caused increased attention to be paid to questions of health in relation to marriage and the propagation of the human race, and anything which helps to spread abroad an intelligent appreciation of the dangers incurred, not only by individuals who enter on the married state but also by their offspring, from the existence of many forms of disease, must be regarded as a public benefit. The present book is an attempt to make available for general consumption the gist of the larger work from which it is taken. Details of cases and some matter not suitable for the general reader are omitted but the plan of the work is the same and most of the articles appear to be little altered. After an introduction by Professor Senator we find articles by Professor M. Gruber on the Hygienic Significance of Marriage; by Professor J. Orth on Consanguineous Marriages; by Dr. W. Havelburg on Climate, Race, and Nationality; by Professor P. Fürbringer on the Sexual Hygiene of Married Life; and by Professor R. Kossmann on Menstruation, Pregnancy, and Lactation in relation to this state. Chapters follow dealing *seriatim* with diseases of the various bodily systems as they affect married persons and their offspring; among these Professor A. Neisser deals with gonorrhœal affections and Dr. R. Ledermann with syphilis. Professor C. Posner writes on disorders of the lower uro-genital organs and impotence, and Dr. L. Blumreich on diseases peculiar to women, including sterility. Insanity in relation to marriage is intrusted to Professor E. Mendel and the subject of perverted sexual sensations to Dr. Albert Moll. Drug habits and occupational diseases are dealt with by Messrs. A. and F. Leppmann and medico-professional secrecy by Dr. S. Placzek.

The material contained in the book is most valuable and a study of it should be useful to those capable of appreciating it. We doubt, however, whether the book is adapted to appeal to a wide circle of readers. It is a volume of considerable size and costs half a guinea net. It contains a large proportion of matter which is "caviare to the general," such as tables of statistics and a consideration of a number of diseases which can only be recognised by a medical man and about which, therefore, the patient will have to seek medical advice. It might then be safely left to the medical profession to give advice on such matters. We should have preferred for popular use a smaller volume containing information in a much more condensed form. The diseases which are of special importance in relation to the married state could then have been dealt with epidemic diseases, against 366, 341, and 397 in the three preceding weeks; of these, 123 resulted from whooping-cough, 113 from measles, 73 from diarrhœa, 38 from scarlet fever, 35 from diphtheria, and 14 from "fever" (principally enteric), but not any from small-pox. No death from any of these epidemic diseases was registered last week in Willesden, Brighton, Tottenham, Leyton, Birkenhead, Halifax, or in 11 other of the 76 towns; the annual rates from these diseases, however, ranged upwards to 3·5 in Wigan, 3·6 in Preston, 3·7 in Grimsby, in Derby, and Gateshead, 4·3 in Walsall, and 4·4 in Cardiff. The 123 deaths from whooping-cough were 16 in excess of the number in the previous week; the highest rates last week from this disease were 2·7 Walsall, 2·9 in Derby, and 3·1 in Cardiff. The fatal cases of measles, which had been 127 and 142 in the two preceding weeks, declined again to 113 in the week under notice, and caused death-rates ranging upwards to 1·8 in Wigan and in Preston, 2·0 in Great Yarmouth, and 2·2 in Grimsby. The deaths from diarrhœa, which had been 39 and 65 in the two preceding weeks, further rose to 73 last week, the highest death-rates being 1·1 in Walsall and in Bolton, 1·2 in Rhondda, and 1·3 in Devonport. Scarlet fever caused a death-rate of 1·5 in Grimsby and diphtheria a rate of 1·1 in Wigan. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospital and the London Fever Hospital, which in the 11 preceding weeks had risen successively from 2658 to 3387, had further increased to 3586 at the end of last week; 557 new cases were admitted during the week, against 504, 493, and 569 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had declined from 156 to 126 in the four preceding weeks, rose again last week to 136, and exceeded by 19 the corrected average number in the corresponding week of the five years 1902–06. The causes of 36, or 1·0 per cent., of the deaths registered in the 76 towns during the week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Sheffield, Bristol, West Ham, Newcastle-on-Tyne, Hull, and in 50 other of the 76 towns; the highest proportions of uncertified deaths were recorded in Liverpool, Manchester, South Shields, Coventry, and Burton-on-Trent.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 13·7 and 14·9 per 1000 in the two previous weeks, declined again to 13·6 per 1000 in the week ending July 27th, but was 1·7 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 9·0 in Perth and 9·3 in Aberdeen, to 15·3 in Paisley and 15·8 in Edinburgh. The 474 deaths in these towns showed a decrease of 44 from the number in the previous week, and included 66 which were referred to the principal epidemic diseases, against 59, 60, and 63 in the three preceding weeks. These 66 deaths were equal to an annual rate of 1·9 per 1000, which exceeded by 0·6 per 1000 the rate from the principal epidemic diseases in the 76 large English towns; they included 30 which resulted from whooping-cough, 15 from "fever," ten from diarrhœa, five from measles, three from scarlet fever, and three from diphtheria, but not any from small-pox. The fatal cases of whooping-cough, which had been 18, 22, and 23 in the three preceding weeks, further rose last week to 30, of which 13 occurred in Glasgow, eight in Edinburgh, three in Dundee, two in Paisley, two in Leith, and two in Greenock. The deaths referred to different forms of "fever," which had been 14 in each of the two preceding weeks, rose to 15 last week, and included seven cases of cerebro-spinal meningitis in Glasgow, three in Dundee, and one in Leith. The fatal cases of diarrhœa, which had been 12 and 19 in the two preceding weeks, declined again last week to 10, of which four were registered in Glasgow, three in Dundee, and two in Edinburgh. The deaths from measles, which had been eight and seven in the two previous weeks, further fell to five last week and included four in Glasgow. Two of the three deaths from scarlet fever and two of the three from diphtheria also were registered in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, which had been 80, 88, and 72 in the three previous weeks, further declined to 63 in the week under notice, but were 11 in excess of the number in the corresponding week of last year. The causes of 12, or 2·5 per cent., of the deaths registered in the eight towns during the week were not certified or not stated; in the 76 English towns the proportion of uncertified deaths did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 21·0 and 21·5 per 1000 in the two previous weeks, declined again to 21·2 per 1000 in the week ending July 27th. During the first four weeks of the current quarter the death-rate has averaged 20·5 per 1000, the rate during the same period being only 12·0 per 1000 in London and 14·5 in Edinburgh. The 159 deaths of Dublin residents registered during the week showed a slight decline from the number in the previous week, and included 12 which were referred to the principal epidemic diseases, against 19, 14, and five in the three preceding weeks; of these, four resulted from whooping-cough, four from diarrhœa, three from measles, and one from "fever," but not any from small-pox, from scarlet fever, or from diphtheria. These 12 deaths were equal to an annual rate of 1·6 per 1000, the death-rate during the same week from the principal epidemic diseases being 1·4 in London and 2·3 in Edinburgh. The fatal cases of whooping-cough, which had been nine, seven, and four in the three preceding weeks, were again four in the week under notice; the mortality both from measles and diarrhœa, however, was in excess of the average for the three preceding weeks. The 159 deaths from all causes in Dublin last week included 35 of children under one year of age and 35 of persons aged upwards of 60 years; the deaths of infants slightly exceeded the number in the previous week, while those of elderly persons showed a marked decline. Five inquest cases and five deaths from violence were registered; and 54, or nearly 34 per cent., of the deaths occurred in public institutions. The causes of five, or 3·1 per cent., of the deaths in Dublin last week were not certified; the percentage of uncertified deaths in London was 0·2 and in Edinburgh 1·0. The 117 deaths in Belfast included 12 which were referred to cerebro-spinal fever or cerebro-spinal meningitis.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff-Surgeon: R. J. MacKeown to the *Thetis*, on re-commissioning. Civil Practitioner W. Drake to be Surgeon and Agent at Harwich.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon Charles William Buchanan-Hamilton has been placed on the Retired List, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Charles R. Woods retires on retired pay (dated July 27th, 1907).

Captain A. H. Morris has joined the Scottish Command for duty as sanitary officer, vice Captain C. F. Wanhill who has joined at the Royal Army Medical College, London, for duty. Major C. E. P. Fowler, assistant professor of hygiene at the Royal Army Medical College, has been appointed for special duty at Gibraltar.

The following officers have been appointed to the Irish Command: Captain H. P. W. Barrow, Captain H. S. Taylor, Captain T. E. Fielding, and Captain A. D. Waring to Dublin; Captain W. Bennett and Captain G. Carroll to Cork; and Captain J. H. Barbour to Belfast.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Kent: Surgeon-Lieutenant-Colonel R. R. Brown is granted the honorary rank of Surgeon-Colonel (dated July 1st, 1907). *3rd Middlesex*: Thomas Jefferson Faulder to be Surgeon-Lieutenant (dated July 9th, 1907).

DEATHS IN THE SERVICES.

Surgeon-General Alexander Francis Preston, A.M.S., honorary physician to the King, at his residence in Redcliffe-gardens, South Kensington, recently, at the age of 65 years. He joined the service in 1863 as assistant surgeon, became surgeon in 1873, and reached the rank of surgeon-general in 1898. He retired on half-pay in 1902. He served in medical

13 lithographic representations of the fundus accompany this article. 5. Some Unusual Ocular Manifestations of Gonorrhœa, by W. Campbell Posey, M.D , of Philadelphia. 6. A Report of Two Cases of Parinaud's Conjunctivitis, by Frederic Krauss of Philadelphia. 7. The Ocular Symptoms in a Case of Tumour of the *Pituitary Body*, by Howard F. Hansell, M.D , of Philadelphia. 8 Conjugate Palsy of the Upward and Downward Movements of the Eyes, by C. E. G. Shannon, M.D., of Philadelphia. 9. A Modified Paquelin Cautery for Ophthalmic Use, by Edward B. Coburn, M.D., New York. In addition, this number contains abstracts from English and continental journals.

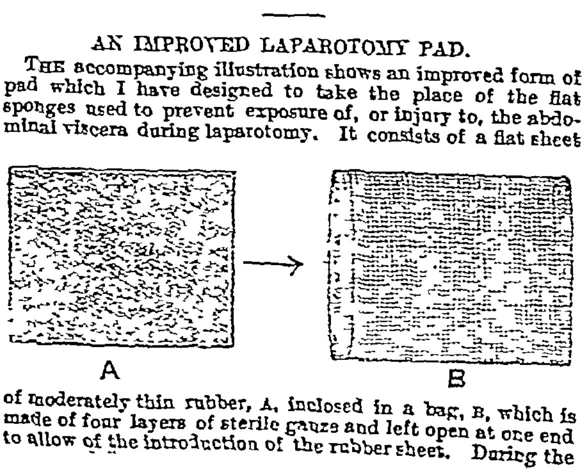
Annals of Otology, Rhinology, and Laryngology, March, 1907.—There are 19 original articles in this issue of a valuable periodical—the last, we may mention, to reach our hands despite the date which appears upon it. The most important article is by Zwaardemaker on the Determination of Aural Acuity by Means of the Whisper Test. It is a very interesting article but loses much of its value to the English-speaking aural surgeon owing to the fact that the tests are made out in French, German, and Dutch. Nevertheless, it is extremely valuable and it is to be hoped that it may lead to similar groups of words being evolved in the English language. Another article which must attract a certain amount of attention is by W. S. Anderson on the importance of correcting pathological conditions of the nose and throat in patients who have incipient tuberculosis. As this article deals with a contentious question, involving the whole principle as to whether it is advisable or not that operations should be performed which are not necessary for the life of the patient if the patient be suffering from tuberculosis, it requires more than the final paragraph, in which the writer states that "the value of these operations is not proven," to show that this is a correct decision in cases of this description.

Annals of Tropical Medicine and Parasitology. Vol. I., No. 2. Illustrated. Pp. 119. Price 7*s.* 6*d*. (Issued by the Liverpool School of Tropical Medicine.)—Two of the most interesting contributions contained in this number of the "Annals of Tropical Medicine and Parasitology" are on Trypanosome Transmission Experiments by the late J. Everett Dutton, M.B. Vict., J. L. Todd, B.A., M.D., C.M. McGill, and J. W. B. Hanington, M.D. McGill., and Concerning the Treatment of Experimental Trypanosomiasis, by Professor Benjamin Moore, M.A., D.Sc., M. Nierenstein, Ph.D., and J. L. Todd, B.A., M.D., C.M. McGill. The former contains the description of a number of experiments and observations which suggest very strongly that sleeping sickness must be conveyed in some other manner besides the bites of flies. The experiments showed that it is only with the greatest difficulty and in particular circumstances that infection can be brought about by the bites of infected tsetse flies. Furthermore, in places where sleeping sickness has in recent years spread very considerably, so that a large percentage of the population is infected, the tsetse fly is comparatively rare. From their experiments and observations the authors conclude: 1. Mammalian trypanosomes may be mechanically transmitted by the bites of blood-sucking arthropoda. 2. A cycle of development of the trypanosomes exists in which occur spherical parasites formed by the throwing off of blepharoplast, undulating membrane, and flagellum. These forms exist in both the vertebrate and invertebrate host; conjugation probably plays no part in the production of this form. A possibly distinct cycle is represented by the spherical parasites, consisting almost entirely of nucleus, which result from the disintegration of trypanosomes. 3. There is reason to suspect that a sexual cycle may also occur, it may be in either or in both hosts. 4. The rapid spread of sleeping sickness cannot be fully explained by (1) alone; the cycles of development mentioned in (2) and (3) probably play a very important part in the transmission of the disease. In the second article above referred to the results obtained in the treatment of trypanosomiasis in various animals are very remarkable. The treatment with atoxyl first suggested by Thomas and Breinl was used. This was followed by treatment with perchloride of mercury. Both drugs were given subcutaneously. The authors point out that the solution of atoxyl (5 per cent. in sterile water) deteriorated rapidly, particularly when exposed to light. The deteriorated solution is highly toxic in its effects. The experiments show that in rats infected with *Trypanosoma brucei* and treated with atoxyl alone, the trypanosomes, after disappearing from the peripheral circulation, reappeared in from 16 to 25 days. Of 113 rats treated, only three remained alive at the time the paper went to press. In 25 rats the perchloride of mercury was used after the trypanosomes had disappeared from the peripheral blood under the action of atoxyl. Of these 13 were still living (after from 56 to 181 days), while all the controls which received at the same time the same quantity of atoxyl alone were long since dead. In several cases, however, among the 25 the treatment was not commenced until the animals were almost moribund and so these might probably be neglected. Others, again, probably died from the effects of the drugs. These results are most encouraging and it seems eminently probable that when this treatment is used upon cases of sleeping sickness it will be found satisfactory. An automatic oiler for the destruction and prevention of mosquito larvæ in cesspools and other collections of water is described by E. H. Ross and H. C. Ross. The apparatus is of the simplest nature and could be made in any part of the world without difficulty. It saves a large amount of the waste necessarily involved by using paraffin in the ordinary manner, and as its action continues over many months it also saves a vast amount of labour. The cost of each oiler is about sixpence. A contribution on the Anatomy of the *Proboscis* of Biting Flies, Part II., Stomyxs (Stable Flies), by J. W. W. Stephens, M.D. *Cantab.*, and R. *Newstead*, A.L S., F.E.S., is of considerable interest. The accounts of the mouth parts of stomyx hitherto available have been incomplete and inaccurate, and now that it is known that parasitic infection is so often brought about by the bites of arthropods it is desirable that accurate accounts of their anatomy should be available. The value of the contribution is considerably enhanced by numerous admirable illustrations. Another contribution deals with Cattle Trypanosomiasis in the Congo Free State.

New Inventions.

AN IMPROVED LAPAROTOMY PAD.

THE accompanying illustration shows an improved form of pad which I have designed to take the place of the flat sponges used to prevent exposure of, or injury to, the abdominal viscera during laparotomy. It consists of a flat sheet of moderately thin rubber, A, inclosed in a bag, B, which is made of four layers of sterile gauze and left open at one end to allow of the introduction of the rubber sheet. During the



as possible into the country where they spend a happy fortnight amid country scenes with country hosts. Last year the public enabled the fund to send away over 43,000 children. This year still more are asking for the holiday, and for months past have been saving up their pennies towards the cost of it, while their mothers have done their best to equip them with the simple outfit required.

The first party of 20,000 started on Thursday last, all bearing distinctive labels showing their destination, and thanks to the kindliness of the railway companies all have arrived safely at their destination. There are still another 20,000 hoping to go on August 8th, and to pay for them the fund requires at least another £8000. Subscriptions at present are behind those of previous years so the need of support is urgent. The risks of the holiday are so small, the results so beneficial, that I earnestly hope the generosity of the public will secure that as few as possible of these children will be disappointed. The offices of the fund are at 18, Buckingham-street, Strand, W.C., and the honorary treasurer is the Earl of Arran. One guinea will send away two children for a fortnight.

Your obedient servant,
A. F. LONDON.

18, Buckingham-street, Strand, W.C., July 27th, 1907.

EXPERIMENTS ON PROLONGED PROTEIN FEEDING.

To the Editors of THE LANCET.

SIRS,—In your issue of to-day is a letter from Dr. Chalmers Watson in which he raises certain points in connexion with the experiments recorded in my paper with the above title that was published in THE LANCET of July 20th last. With your kind permission I should like to reply briefly to these points.

Dr. Watson is of opinion that my experiments are not comparable to his own because he notes two points of difference in their details. In his experiments which "were directed to ascertain the effects of an exclusive meat dietary ...... the food was given in an uncooked condition in order that all the nutritive juices and soluble salts of the meat should be consumed by the animals," whereas in my experiments the meat diet was supplemented "by the addition of inorganic salts and possibly other foodstuffs and the meat was cooked." When I first read Dr. Watson's original paper I was at once impressed by the fact that he had made insufficient provision for his birds in the matter of lime and it seemed to me that many of the effects he ascribed to excess of meat were possibly due to this omission. In repeating his experiments special care was therefore taken to provide, in addition to the meat, an ample supply of lime (but absolutely no other foodstuff) with the result that no symptoms of leg weakness appeared and no changes in the bones resulted. The two observations that fowls fed on meat alone developed changes in their osseous systems and that fowls fed on meat plus lime developed no such changes can, I think, be most profitably compared, inasmuch as they show that the bone changes are the result not of excess of meat but of want of lime. It is important that this deficiency which an exclusive meat diet necessarily entails should be fully recognised and provided for. I am glad to hear from Dr. Watson that he recognised from the first this result of his diet, because the fact that in none of his original contributions on the subject is the lime factor mentioned is apt to leave his readers in doubt as to whether its importance had been realised at all.

As regards the partial cooking of the meat in my own experiments, it was stated in my paper that at first butchers' trimmings (i.e., raw meat) were given, but that on the score of expense half-raw horseflesh was substituted. On referring to Dr. Watson's original paper it appears that he administered at first raw ox meat but later gave cooked horseflesh for a time, abandoning the latter because it was difficult to obtain and was not readily taken by his animals. In his experiments Dr. Watson clearly attached but little importance to the raw state of his food. I do not think that this single distinction can be responsible for the differences in our results and I believe that Dr. Watson will agree with me in this, seeing he has applied the results of his raw-meat experiments to the question of meat eating in man with whom, of course, this food is practically always fully cooked.

In dealing with the hypertrophy of the thyroid glands Dr. Watson admits that his observations are not as complete as they should be and that the various fallacies mentioned in my paper had suggested themselves to him. Yet without supplementing the former or excluding the latter he holds that his is the only possible conclusion. It is disappointing that Dr. Watson should be content to draw a definite conclusion under these conditions, for his work on the subject has been of great interest not only from an experimental but also from a clinical point of view and one cannot but feel that he may needlessly endanger the value of his results by leaving his data thus insecure from criticism. I hope, however, that the importance of the question may induce him to repeat his experiments with a view to confirming, or if necessary modifying, his conclusions which differ from those obtained by all other investigators.

Dr. Watson believes that "more than one of the five appearances illustrated" in my paper "are pathological." Though I have examined the thyroids of more than 70 different species of animals I had not been able to recognise any pathological changes in the specimens selected as illustrations but have found that variations in structure between the Elenora falcon type and the ostrich type are by no means rare either in mammals or in birds. I should, however, be very glad if Dr. Watson would give me the benefit of his own experience, showing which specimens are pathological and how the changes can be recognised as such. I may add that I have had the opportunity of examining the thyroids of three full-grown two-spotted paradoxures (Nandinia binotata), in the first of which the thyroid was vesicular, in the second partly vesicular and partly non-vesicular, and in the third non-vesicular, yet all three animals had been kept under identical environmental conditions as regards climate, atmospheric temperature, cleanliness, character and quantity of food, water-supply, &c.

I am, Sirs, yours faithfully,
DAVID FORSYTH.

Harley-street, W., July 27th, 1907.

SOME PHYSIOLOGICAL EFFECTS OF HIGH-FREQUENCY CURRENTS IN DISEASE.

To the Editors of THE LANCET.

SIRS,—I am obliged to Dr. S. Sloan for the data he has so kindly given regarding his apparatus in THE LANCET of July 13th, p. 111. With regard to the application of high-frequency currents to the body, apart from the state of the latter, it is essential that five factors be considered—viz., voltage, ampèrage, wattage, time, and frequency—if a true estimate of their physiological effects upon the body is to be obtained, and in order that the latter be correctly computed it is essential that the wattage be based upon ampèrage. Dr. Sloan, however, has not considered this necessary. The frequency of the current is simply a condition to enable the current to be applied to the body with safety. If the particulars he has given as to the voltage and ampèrage of his apparatus are to be adhered to, then I contend that it is impossible for the body to withstand the wattage of the apparatus. The apparatus takes a voltage of 250, with an average of five ampères. This reduced to ordinary formula equals 250 × 5 equals 1250 watts on the primary side of the apparatus. This is transformed to 500 milliampères at 80,000 volts equal to 80,000 × 500 divided by 1000 equals 40,000 watts.

From a purely physical standpoint no one would contend that this wattage could be safely applied to the body. Should it still be contended that the voltage on the secondary side is 80,000, then the ampèrage is equal to approximately 16 milliampères and not 500. On the other hand, if it is held that 500 milliampères are taken out of the secondary circuit, then the voltage is only 2500 as the following equation will show: 2500 × 500 divided by 1000 equals 1250 watts, which is equal to the wattage on the primary side of the apparatus without taking into consideration the possible loss in efficiency of 15 per cent. by transforming.

The question naturally arises, under which of these three conditions have Dr. Sloan's experiments been carried out? It is evident that Dr. Sloan has either been working with virtually a low potential current or if a high potential, that little or no current was being passed through the body, regardless of what was being registered on the milliampère-meter. With reference to the drop of potential observed by him when carrying out his experiments, I respectfully submit

THE LANCET.

LONDON: SATURDAY, AUGUST 3, 1907.

The Addresses before the British Medical Association: A Plea for Accuracy in Medicine.

We report on other pages of this issue the three addresses delivered in plenary congress at the seventy-fifth annual general meeting of the British Medical Association at Exeter. We are enabled to do this by the courtesy and assistance of the editor of the *British Medical Journal*. The Presidential address of Dr. Henry Davy deals with Science in its application to National Health, Dr. W. Hale White in his address in Medicine puts forward a plea for Accuracy of Thought in Medicine, whilst Mr. H. T. Butlin has chosen as the subject of the address in Surgery the Contagion of Cancer in Human Beings, especially from the Point of View of Auto-Inoculation. In considering these discourses, with no disrespect to Dr. Davy's excellent and timely address, we propose to discuss first the strong appeal made by Dr. Hale White for accuracy of thought in medicine, as in some sense pointing the moral of the trilogy. The general effect that the reading of Dr. Hale White's address will probably leave on most medical men is one of salutary humiliation, for he irresistibly brings home the truth that only too often does the voice of authority seek to expound a mystery by giving it a name, and only too readily does contemporary medical thought abase itself before the words of the oracle.

He begins his indictment by considering that nebulous clinical scapegoat which is known as "irregular gout," and insists that not a few practitioners when confronted with certain unexplained symptom-groups, instead of humbly confessing to ignorance of their nature and seeking by increased diligence to search out their causes, think to explain them away by assuming that such symptoms would be caused by an excess of uric acid in the patient's blood and by further assuming that such an excess of uric acid exists in that blood; their next step is to assume that this state of things is brought about by consuming "red" meat or by not consuming "white," and so the chicken is allowed and the beef-steak forbidden. When we see the premisses of these not infrequent clinical and therapeutical deductions thus exposed we are constrained to support Dr. Hale White's suggestion that in certain matters we have not advanced beyond the tenth century, although in many more the progress of our science has been so remarkable. The next example of inaccuracy in medicine that comes under Dr. Hale White's scourge is the slovenly diagnosis of a "liver out of order"; and had he been again historically minded, he might have traced that diagnosis *de convenance* at least as far back as the fourteenth century. He proceeds to show how by the blind acceptance of the symptom of hæmatemesis in a young woman as the inevitable witness to an ulcer in her stomach many patients have been submitted to a severe and useless treatment, while it is clear that the plain evidence of the post-mortem room to the existence of "gastrostaxis" as a clinical entity has been overlooked by clinicians for a needlessly long time. The next object of attack was the doctrine of "selective action" of diseases on different tissues, and here again Dr. Hale White does good service in reminding us that the name does not explain the fact. His warning against making a diagnosis which implies a cause, unless that cause has been verified as really present, is worth quoting: "We shall often have to say that we do not know, but at any rate our reticence will not retard but will rather advance the progress of medicine." He might have cited the whole history of mediæval medicine in support of the mischief wrought by an inability of its practitioners ever to confess their ignorance. The last word of this stimulating sermon is directed against the blind belief in authority, and no better instance could have been given than the abuse of venesection, though Dr. Hale White does not forget to add a plea for the disregard of the reactionary voice of modern authority that has attempted to abolish bleeding entirely. Let us give another instance of the abuse of authority that readily occurs, and one which tends most terribly to inaccuracy in medicine. The copying of time-honoured errors and unfounded speculations from text-book to text-book is a practice of which modern writers have by no means purged themselves. Here we are addressing mainly the leaders of the profession, and it is good that salutary words should be addressed to them as much as to the rank and file. We all want accuracy, and the longest step towards gaining it has been taken when we recognise how easy it is to be inaccurate.

Dr. Davy, at the outset of his Presidential address reminds his audience that the enormous changes which had occurred in the practice of medicine since the British Medical Association met 65 years ago at his ancient city were due to "the growth of knowledge founded upon systematic experiment—that is to say, scientific knowledge." Systematic experiment has only one object, the accurate observation and recording of facts and the deduction of principles from their sequences, and if at the outset accuracy be wanting then the deductions drawn can only leave confusion worse confounded. He would be a bold man who would deny that in some instances this has happened in modern medical progress, but the solid mass of scientific truth which these 65 years have given us rests entirely upon the foundation of accurate method and accurate thought. We may read the same lesson into much of Dr. Davy's address, although he concerns himself rather with the state of the national health than the advance of experimental science in the present day. Thus when he discusses the advantage of physical exercises as a means of training the body he laments that the instruction of the people in such means of attaining to and preserving its health should be left to "professors of Swedish exercises" instead of being directed by its medical advisers; this surely means that it is in the accurate adjustment of such training to the needs and limitations of the individual that the greatest too difficult for the *average man*. 2. Selection of an easy living language. This also has the experience of centuries against it. No living language is easy enough. No living language can surmount the barrier of international jealousy. 3. Invention of an easy and neutral language. This has been attempted some hundreds of times. Naturally, all these artificial languages have been neutral enough, but so far only one has been easy enough. And this unique language is Esperanto.

Its easiness.—That Esperanto is easy anyone may prove to himself at the cost of a few pence and a few minutes. Its inventor says, "My whole grammar can be learned perfectly in one hour." Leo Tolstoy says that in two hours he was able to read Esperanto fluently. Sir William Ramsay says that an English child in six months can read, speak, and write it. My own experience is confirmatory so far as reading is concerned, but, of course, accurate writing is more difficult and fluent speaking is more difficult still. Yet by dint of teaching a class I have satisfied myself that illiterate Englishmen can acquire the language in an astonishingly short time.

The simplicity of Esperanto depends on the following facts: 1. All international words are transferred to Esperanto with merely a phonetic modification—e.g., teatro, telefono. This practice is an especial boon to the reader of medical literature, for in such writings international words bulk largely. 2. There is a groundwork of easy root words (about 2000), most of which are known already to an educated man. 3. These are varied by the addition of about 36 affixes, whereby extraordinary precision and most copious diction are attainable. 4. Grammatical inflections are cut down to the minimum, and, being based on the vowels a, e, i, o, and u, they are easily remembered as well as euphonic. 5. Pronunciation is unmistakeable. It is rigidly phonetic. Each letter is sounded. The word-stress is always on the second-last syllable.

Its adequacy.—That Esperanto is adequate for converse between doctor and patient follows from the fact that it is adequate for all the ordinary relations of life. Recently on being introduced to a young German who knew no English, I found that we were mutually comprehensible in Esperanto. Here is another testimony: "Yesterday a young man comes to my house and asks to speak with me. I meet him, and he greets me forthwith in Esperanto. It is a young Russian. He knows not a word of French, I cannot speak a syllable of Russian. But we had our dear *lingvo internacia* in which we conversed for a good hour without even noticing any difference in our mode of pronunciation. And yet we had learned it by ourselves, from a little text-book, thousands of miles from one another." (M. d'Eyssautier.) Here is yet another witness: "I can prove to our sceptical friends that, without knowing a single foreign language, I am corresponding with persons of 17 different nationalities, amongst whom are to be found Frenchmen, Germans, Englishmen, Swedes, Norwegians, Italians, Spaniards, Portuguese, Americans, Africans, &c." (Dr. J. Ostrovski.) Moreover, those who have taken part in the various international Esperanto congresses aver that they have had no difficulty in conversing on all imaginable subjects with Esperantists of most diverse nationality. That Esperanto is adequate for use in international medical congresses follows also from its success in the various Esperantist congresses. At Dover in 1904 five nations took part; at Boulogne in 1905 22 nations took part; and at Geneva in 1906 23 nations took part. Speeches, debates, and business, as well as concerts and plays and social gatherings are all easily practicable in Esperanto.

That Esperanto is adequate for the purposes of medical literature can be learned from the study of one number of the *Internacia Revuo Medicina*.[1] Thanks to the number of international words in medical writings any practitioner ought to be able to read this *Revuo* with no better aid than a halfpenny key to Esperanto. Then he will see that Esperanto can express all that English or French can convey and the parallel columns will prove to him that it is more terse than either. Indeed, considering that the inventor of Esperanto, Dr. Ludovic Zamenhof, is a practising medical man, it is only to be expected that the language should be suitable for medical purposes. Growing numbers of practitioners have been learning it in Britain and far greater numbers have mastered it abroad. An Esperanto medical dictionary is in preparation.

Suggestions.—I have tried to show that Esperanto may prove useful in the course of medical practice, that Esperanto must prove useful at international medical congresses, and that Esperanto has proved useful in the publication of international medical literature. I would suggest, in conclusion: 1. That Esperanto should be made a compulsory subject in our medical preliminary examinations, and that in all medical schools the students should be encouraged to read, and write, and speak in Esperanto. This, with their native tongue, will suffice them for scientific purposes all the world over and will save them their laborious yet unfruitful study of the other modern languages. 2. That Esperanto should be adopted as an official language at international medical congresses. It will speedily oust its rivals. 3. That, as a preparatory measure, each nation should appoint a standing medical literature committee, which would annually decide what among the records published in its mother tongue are of permanent value, and would forward that material to an international committee for republication in Esperanto.

As a hobby.—But it would be unfair to close without a word or two on the attractiveness of the study of Esperanto as a hobby for medical men. It is a quiet and clean occupation; it can be pursued in the pauses of one's practice; it is in itself a keen intellectual pleasure; it opens up a wide and curiously varied range of literature; it throws a marvellous light on our English language, on grammar, and on points of style. Withal, proficiency in this language is rapidly attainable; every one may reasonably count on mastery; and then there comes the strong delight of wielding skilfully this brilliant, supple, clear, and comely mental tool. Further, Esperanto broadens a man's outlook; it can give to the loneliest country doctor correspondents and human interests in every quarter of the globe; it can make him indeed a citizen of the world and a universal brother. More than that, it has realised to such an extent the vague, expectant aspirations of our time that for many a man and woman, even now, it shadows forth the coming world religion.

I am, Sirs, yours faithfully,
W. WINSLOW HALL, M.D. Edin.,
Diplomito de la Brita Esperantista Asocio.
July 20th, 1907.

BEES' STINGS AND RHEUMATISM.

To the Editors of THE LANCET.

SIRS,—In connexion with the correspondence which has appeared in your columns upon the subject of bees' stings and rheumatism, it is interesting to recall that several years ago a patient wrote me asking whether physicians of to day continued to use bees for stinging the inflamed joints in rheumatism as a curative measure, stating that he had read in an ancient classic, the reference to which I have forgotten, that such treatment was practised along the eastern shores of the Adriatic, I believe, at some time prior to the Christian era.

I am, Sirs, yours faithfully,
EDWARD F. WELLS, M.D.
Chicago, June 17th, 1907.

THE SHADOWGRAPH BOUGIE IN URETERIC SURGERY.

To the Editors of THE LANCET.

SIRS,—Few surgeons, I take it, who are working at renal or ureteric surgery would care to operate without the advantage of a good shadowgraph ureteric bougie. In a small number of cases the bougie is indispensable, for it enables the surgeon to detect false radiographic shadows and thus to avoid an extensive exploration upon the pelvic part of the ureter.

Unfortunately, a foreign firm has placed upon the market a shadowgraph ureteric bougie which exactly resembles the bougie used in England, the Marshall shadowgraph bougie. A foreign specimen was handed to me and to prove its value I placed it and a Marshall bougie on a radiographic plate. The foreign-made bougie left a faint shadow but the Marshall a strong black shadow. To obtain the best results it is necessary to secure the Marshall or one which casts an equally strong shadow.

I am, Sirs, yours faithfully,
E. HURRY FENWICK.
Savile-row, W., July 22nd, 1907.

[1] Paris: 33, Rue Lacépède; monthly, 1s.

artificial barriers, purporting to divide the medical profession into classes and sections, is for the good of the profession and the public."

Turning now to the Cheltenham General Hospital, we find that although that institution relaxed its original rule so as to throw open its physicianship to any registered British graduate or Fellow, Member, or Licentiate of a College of Physicians of the United Kingdom, yet the practice of surgery, pharmacy, or midwifery was made a disqualification for the appointment. In this instance, then, we find a very rigid rule adopted, and it is, we understand, strictly administered, so that presumably the opening of an empyema would be held to be beyond the physician's pale. Moreover, he is, of course, entirely debarred from the private pursuit of general practice. This restricting regulation is strictly comparable to the "Membership qualification" which has been rescinded at Hastings, wisely as we think. The only difference between them is that the one lays down the written law that the hospital physician shall practise "medicine" only, and the other relies on the restrictions attached to the possession of the "Membership" that its holder shall confine his practice in like manner; the latter qualification also prevents its owner from practising in partnership, from buying or selling a practice and from suing for fees, all of which must tend to force him into consultant practice. But the demand for pure consultants in the smaller provincial towns which have no medical schools is getting less and less, and the great proficiency to which in the course of the last 20 years the general practitioner has attained, together with the improved facilities of travelling for consultations to London or some other large centres, sufficiently explains this change. Many provincial hospitals, indeed, have never demanded consultant rank of their physicians, but there seems every likelihood that in the future more of those which now insist on the "Membership qualification" may have to follow the example of Hastings, and we think that in so doing they will be ill-advised to add such a restricting clause as has been done at Cheltenham. The situation that is likely to arise in such towns is that which the Hastings, St. Leonards, and East Sussex Hospital has had to face, that no Fellow or Member of a College of Physicians is available to fill a vacancy at the hospital; the only alternative to abolishing the "Membership qualification" would then be the importation of such a Fellow or Member into the town. In probably every case the feeling of the local medical men, many of whom would surely be skilful and competent physicians, would set dead against the latter course, and it is not very likely that the newcomer would prove very successful as a pure consultant.

Supposing that the "Member" should be imported or that there should happen to be a "Member" living in the town who would accept office, it is at least possible that these gentlemen might not be the best men available for the post. The Membership of a College of Physicians is an honourable estate and is the hall-mark of a high standard of professional knowledge attained at one period of its owner's life, but it is no proof that he has kept in touch with the advance in medicine or that he has the love of his work or the tact and address that are all so desirable in a hospital physician; all these, in truth, he may have, but a dozen general practitioners in the town—excellent physicians and surgeons—may have them in yet greater degree, and it surely would be wiser for a body of governors to appoint a man who, of its own knowledge, possessed them than to import a stranger simply because he presented the academic qualification to act as hospital physician. In one other respect the convention is quite illogical; although the surgeons of the metropolitan hospitals and those of the large towns practise "pure surgery," yet they do so by virtue of their opportunities and not of the Fellowship of their College; many of their provincial compeers who act as surgeons to the hospitals of their own towns are general practitioners in the best sense of the word, and neither their College nor their hospital says them nay. Why, then, should their medical colleagues be hampered by an obsolete restriction? We more than suspect that this is a relic of the old-time vaunt of superiority of medicine over surgery, and we cannot refrain from recalling Professor CLIFFORD ALLBUTT'S forcible indictment of ancient prejudices, to be found in his address on "The Historical Relations of Medicine and Surgery," delivered a few years ago at St. Louis—"To maintain separate Colleges to intensify schism ...... to distribute half of a malady to one practitioner, to another the remnant ...... is contrary to art, nature, and common sense." When we consider the excellence of those exponents of medicine, the general practitioners of our provincial towns, it seems unreasonable that regulations made before the present standard of proficiency was attained should hinder their election to the staff of those hospitals which they are so well qualified to serve.

"Miner's Phthisis" at Bendigo.

IN the report of an investigation of the incidence of miner's phthisis at Bendigo, prepared by Dr. WALTER SUMMONS under the direction of the Bendigo Hospital Committee at the cost of the Trustees of the EDWARD WILSON estate, some valuable observations on the prevalence, nature, causes, and prevention of that disease are to be found. A statistical study of the death registers from January, 1875, to July, 1906, showed that there had been a marked increase in the number of miners dying from diseases of the respiratory tract, notably tuberculosis. The number of quartz miners at Bendigo has varied during that period from 2850 to 3990. During the period investigated the total deaths from all causes amounted to 2810, of which 1402 were due to respiratory diseases, 891 being recorded as due to tuberculosis and 280 as chronic bronchitis, although it is probable that the majority of these would be more correctly included as tuberculous. A study of the quinquennial mortality rates brings to light the striking figures that the mortality from respiratory diseases calculated as per 10,000 has risen from 77·0 to 191·6, that from tuberculosis alone having increased from 48·5 to 129·6, the latter figure being six times as great as the mortality rate amongst adult males from pulmonary tuberculosis in Victoria generally. The ill-effects of this prevalence of that disease are shown also among the non-mining inhabitants of Bendigo, who likewise show an excessive death-rate from it in spite of the healthy climate of Bendigo.

THE ORGANISATION OF THE MEDICAL PROFESSION IN IRELAND.

(From our Special Commissioner.)

Dublin, July 27th.

The Irish Medical Association is well satisfied with the progress which it has accomplished during the last few years. Some 20 years ago it barely counted 500 members; it has now 884 members on its books, though some names may have to be struck off as 24 of these have not paid their subscriptions. The association has been in existence for more than 60 years and the subscription is one guinea per annum. It may be said that more than a third of the Irish medical practitioners are organised, and this in one single society. There are 2600 practitioners on the Register for Ireland but it is thought that not more than 2300 are in active practice. The Irish Medical Association is satisfied because its membership is increasing but, as it is a fighting organisation, it is much better pleased because it has been victorious in some notable contests. It is claimed that a sort of renaissance has taken place in the association. Formerly it met only in Dublin but in 1899 the annual meeting was held at Cork, and now every other year the association meets in a provincial town: thus it has been to Belfast, to Enniskillen, and to Portrush. By this means a much greater number of medical men living in the provinces and rural districts were enrolled. The propaganda was brought to their doors. Then during the alternate years, when the annual meeting is held at Dublin, much greater care has been taken to develop the social side of the gathering. At the evening receptions and parties medical practitioners from the provinces are placed in relationship with Government officials and various distinguished persons whom they might not otherwise have been able to meet. This is, at least, agreeable and sometimes useful. Then since 1901 a small journal, published monthly, is issued as the organ of the association and it keeps the members informed as to the contests and the meetings that are taking place. For now some ten years quite a number of branches of the association have been formed in the country and they keep in touch with each other through the central committee and by means of their journal.

One of the principal functions of the association was to act as a legal defence organisation. It was always endeavouring to improve the position of the poorest members of the profession but it did not succeed very often. It would take up a cause affecting at the time perhaps only one individual but in which the whole profession was interested. Thus the certifying for lunacy is a case in point. According to the law a fee of £2 is allowed but many boards of guardians contented themselves with paying only £1. Then, and so that this should not become the general practice, the Irish Medical Association endeavoured to interfere. Formerly the association was merely a fighting body; now, what with its publications, its congresses, and its branch and committee meetings, it has also become an educating body, striving to educate the medical men themselves as well as the members of the boards of guardians, on which so many of them depend, and the voters who elect the guardians. While thus not neglecting the humblest village elector, the association has been equally anxious to establish friendly relations with the Local Government Board for Ireland. By such action the association claims that during the last three years it has increased the income of the medical profession in Ireland to the extent of £30,000 per annum. In the main this result was brought about by bringing a variety of influences to bear on the boards of guardians who constitute in Ireland the chief employers of the medical profession. For instance, under the Education Act children must attend the elementary schools unless they have a medical certificate exempting them from such attendance. But there are not many parents who can afford to pay for such certificates and the boards of guardians in many places give the medical attendant £10 a year for signing the children's certificates. To many medical practitioners who as dispensary medical officers are probably not earning more than £100 a year this extra £10 is a matter of very great importance, but the money is given only as an act of courtesy and not of right.

As there is but little paying private practice to be had in Ireland the position of dispensary medical officer constitutes the economic basis on which the profession rests. In England dispensaries are private charitable or provident institutions. The term "dispensary" has quite a different meaning in Ireland, where the dispensary medical officer is a public functionary employed and paid by the local authority to attend to the poor, not merely paupers but any patient who is content to style himself as a "poor person." The difficulty has always been that of defining what constitutes a "poor person." In practice it seems to mean anyone who is not in exceptionally prosperous circumstances. But the wealthier classes are leaving the country. On the other hand, farmers and persons with small means who used to make an effort to pay their medical attendant are commencing to look upon medical attendance as a public service for which they pay in the form of rates. On the ground that the rates have increased they think that they need not give fees to their medical attendant but are willing to vote in favour of his obtaining an increase of salary. Thus taxation is gradually taking the form of medical insurance. Formerly the local practitioner often treated his appointment to the post of dispensary medical officer as a secondary consideration. His position depended much more on the local magnate and it was fortunate for him if he held the same political opinion. The pay as dispensary medical officer probably did not exceed £100 and the district would be so large that it could not be worked without the aid of a conveyance. But the guinea fees from a section of the population and the fees from the lord of the manor paid for the horse and car, and it was thus possible to do the dispensary work in spite of the smallness of the salary. To-day, however, the lord of the manor has gone and in many rural districts it is difficult to obtain a two-guinea or even a one-guinea accouchement fee. The Poor law guardians themselves, who appoint the dispensary medical officers, sometimes do not hesitate to send an officer a red ticket, which is the regulation urgent form of summons that must be obeyed, and therefore he is compelled to attend on them gratuitously. Thus the dispensary appointment, instead of being a secondary has become the principal consideration, especially in poor and rural districts. Wages have risen, the expenses which a medical practitioner must incur have largely increased, but where the Irish Medical Association has not yet succeeded in bringing about an improvement the salaries paid to the dispensary medical officers remain the same as they were 45 years ago.

The Irish Medical Association is to be congratulated, inasmuch as it has managed to raise the rate of remuneration in 36 Poor-law unions and this affects some 300 to 400 medical men. The increase has also a retrospective effect. Thus it is arranged in many of these districts that the dispensary medical officer should be paid £80 for the first year, with an increase of £10 per annum till the sum of £110 is reached. Those dispensary medical officers who were receiving only £80 a year but had been in the service three years were at once given the £110 a year.

Another great advantage secured is the right to a holiday. Formerly a dispensary medical officer had to continue working till he fell ill and then only could he get away. To-day the majority of the boards of guardians give their dispensary medical officer a month's leave of absence and pay for his substitute, and this is not a sick leave; there is no question of ill-health except in this sense, that a regular holiday taken every year is an excellent method of preventing illness. At the same time a great deal has been done for the young practitioners and others who seek to act as locum-tenents. Formerly they were not paid more than two or three guineas per week. Now the boards of guardians have been induced to give £4 4*s.* a week and where a workhouse is included then it is £5 5*s.*

To obtain these advantages the country was divided into districts and a medical practitioner was appointed as canvasser for each district. He had to call on all the guardians and on all their electors and to explain fully the relative position of the medical profession and of the general public. It was a real educational process in which the medical practitioners were not always the teachers, for the discussion being once open they not infrequently had to hear complaints and criticism formulated against the profession by members of the general public. In spite of all these discussions and efforts the Irish Medical Association has not yet succeeded in effecting any settlement in regard to the superannuation fund. The object is to insure that every dispensary medical officer shall receive a pension on retiring from practice.

recommendations are made in this report: firstly, to endeavour to prevent infection by the tubercle bacillus and, secondly, to prevent the vitiation of the air in the mines by dust and noxious fumes. In regard to the former it is suggested that indiscriminate expectoration and carelessness in the destruction of tuberculous sputum should be penalised, that a home for advanced tuberculous patients and a sanatorium for early cases should be established in the vicinity of Bendigo, that provision should be made for the relief of invalid miners by the Government, and that all miners affected with respiratory diseases should be under medical supervision. It is further recommended that a Medical Inspector of Mines should be appointed. The recommendations as regards ventilation and the prevention of dust are given in a separate report, presented by Dr. SUMMONS to the Department of Mines of Victoria. It is here suggested that certain rules of the Mines Act regarding the allaying of dust shall be rigidly enforced and that the air of the mines shall be tested by inspectors and that where necessary improvements in the construction of air courses shall be enforced. In regard to the dust question, it is shown that dust is formed in most of the operations of mining—viz., in blasting, in shovelling, in throwing the rock and quartz down the shoots, and, above all, in rock drilling. It is essential that in regard to all of these operations the formation of dust shall be minimised or prevented and since water under pressure and compressed air are available in all the mines this should not be difficult to attain. It appears that for some unexplained reason the ordinary miner dislikes using a water jet. We have on a former occasion, in referring to "miner's phthisis" in the South African mines,[1] drawn attention to the importance of the use of a water-jet in connexion with rock drills and this report emphasises the necessity. As in the case of ankylostomiasis an important factor in regard to prophylaxis is to educate the miner himself in regard to the importance of taking precautions respecting his own health. Dr. SUMMONS's reports constitute a valuable and important contribution to the literature of "miner's phthisis" and represent a serious attempt to grapple with a matter of vital importance to the mining community, among whom he has worked. We hope to hear that some, if not all, of his suggestions have been put into effect.

Annotations.

"Ne quid nimis."

THE MIDWIVES ACT, 1902: PAYMENTS SUGGESTED TO THE MEDICAL PRACTITIONERS CALLED IN.

CERTAIN new rules, or modifications of the existing rules, made by the Central Midwives Board in superintending the practice of midwives have been recently approved by the Privy Council and are now being issued by the Local Government Board in a circular to the boards of guardians. The modifications relate largely to midwifery practice in Poor-law establishments, the certified midwives exercising their calling in workhouses or infirmaries under the supervision of a duly appointed medical officer being relieved from the legal compulsions in respect of patient, child, and instruments that are obligatory upon certified midwives attending patients upon their own responsibility. Many of these regulations are, of course, not appropriate in the case of a midwifery nurse in a Poor-law establishment, working under the supervision of a medical officer, nor do some of them apply to midwives exercising their calling in hospitals. The circular of the Local Government Board sets forth the exemptions which would naturally be made in the case of the nursing staff of a hospital. The second section of the circular deals with the appointment of certified midwives in workhouses and infirmaries, which the Board is now prepared to allow, provided that application be made to it, that the proposed midwives be duly qualified under the Act, and further, that the consent of any medical officer entitled to fees for attendance on such cases be first obtained. The last section of the circular states the views of the Local Government Board on the question of payments to medical practitioners called in on the advice of midwives. These views do not constitute a definite instruction on the subject, but the Board suggests that under existing enactments and Orders (Articles 182 and 183 of the General Consolidated Order and Section 2 of the Poor-law Amendment Act, 1848) it is competent to guardians to pay the fee of any medical man called in on the advice of a midwife to attend upon a poor person in case of difficulty. This amounts to little more than a pious opinion, although the further suggestion is made that guardians shall notify to medical men practising in their union willingness to accept the responsibility of fees for attendance on poor women, of whose qualification for such relief the guardians are to be the judge, the payments being on some definite scale suitable to local circumstances. All this does not seem to clear the issue and we are inclined to think that the Board is over-sanguine in its opinion that "the exercise by boards of guardians in a careful but liberal spirit of their powers" should leave no reasonable ground of complaint to the medical profession. We fear that not a few guardians will be inclined to let their carefulness overshadow their generosity, even now that their powers have been more clearly defined by authority.

THE SECOND INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.

WE have already announced many of the arrangements connected with the forthcoming Congress on School Hygiene but it may be convenient to our readers that we should give some final information. The Congress will be formally opened at South Kensington in the buildings of the University of London on Monday next, August 5th, by Lord Crewe, Lord President of the Council, who undertakes the duty at the request of His Majesty the King who is Patron of the Congress. The inaugural address will be delivered by the President of the Congress, Sir Lauder Brunton, at 9 P.M., on Monday, but proceedings in connexion with the Congress will begin on Saturday, August 3rd. Informal receptions will take place on that day at the University buildings from 12 noon till 3 P.M., while from 5 to 7 on the afternoon of the same day there will be a reception at Londonderry House by the Marchioness of Londonderry, the President of the Ladies' Reception Committee. In the evening of August 5th, after the inaugural address has been delivered, there will be a reception and conversazione at the University of London. The sectional meetings will begin on August 6th and will be continued each day from 10 A.M. till 2 P.M. until August 9th. During the afternoons various excursions will be made to places of educational interest, while the evenings, with the exception of August 7th, when official business will be discussed, will be devoted principally to lectures. On August 10th there will be excursions

XII.[1]

EL WEJ: A RETROSPECT.

History of the El Wej Lazaret.—The Constantinople Conference of 1866.—Creation of Camaran Lazaret for Pilgrims going to the Hedjaz and of those of El Wej and El Tor for Pilgrims returning from the Hedjaz.—Unsuitability of El Wej.—A Burst Condenser.—Final Transfer of Pilgrims to El Tor and abandonment of the El Wej Lazaret.—Its Revival proposed to the Paris International Sanitary Conference, 1894, but rejected by the Conference.—Present State of the Town and the remains of the Lazaret.—Conclusion of the Series of Articles.

IF Yanbo is not often visited by Europeans, still more rarely so is El Wej. There is little reason, indeed, why they should go there at the present day. From the sanitary point of view the whole interest of El Wej lies in the past; as a trading port it offers but little importance, and as a port of pilgrimage, though a certain number of Hajjis do pass through it each year, it is not to be compared with either Yanbo or Jeddah. But at one time this small port was a good deal heard of and played a rôle of some consequence in the international prophylaxis of disease in connexion with the pilgrimage. It may be of interest to give, as briefly as possible, the history of the quarantine station there, and to add a few notes on the present condition of the town and on the melancholy ruins which alone remain to mark the site of that station.

The present system of sanitary defence in the Red Sea against the spread of plague and cholera by the pilgrimage dates essentially from the International Sanitary Conference held in Constantinople in 1866. Though not the earliest of these international meetings it was in many ways one of the most historically important, and all the later conferences, ending with that of Paris in 1903, have been but the logical development and continuation of its labours. The list of "conclusions" drawn up by the Constantinople Conference is full of interest even at the present day. They were divided into three groups as follows: (1) those relating to the origin of cholera and its endemicity in India; (2) those relating to its mode of spread; and (3) those relating to practical measures for its control. It is the last group of conclusions alone that need be considered here, and more particularly those relating to the sanitary measures recommended in connexion with the movements of pilgrims in the Red Sea. The most important of these measures was the proposed creation of a large lazaret at or near the entrance to that sea, which was to be under international control and to which all pilgrims coming from beyond the Straits of Bab-el-Mandeb were to be sent to perform quarantine before being allowed to land in the Hedjaz. That proposal ultimately took form in the creation of the Camaran lazaret, so fully described in the earlier articles of this series. It was, and is, intended to prevent the importation of disease *to* the Hedjaz. At the same time it was decided to have two similar institutions near the northern end of the Red Sea, which should protect Egypt, and indirectly Europe, from the danger of the spread of disease *from* the Hedjaz should it become epidemic there during the pilgrimage. One of these was to be established at El Wej and the other at El Tor on the Sinaitic Peninsula. The former port is situated on the Arabian coast, almost exactly opposite Kosseir on the Egyptian shores. The El Wej lazaret was to be employed for quarantining pilgrims returning from the Haj among whom cholera had broken out; that of El Tor for pilgrims free from cholera. Much confidence was placed at that period in long quarantines. Thus in 1867 (though the rules were somewhat modified later) even "clean" pilgrim ships were compelled to do seven days' quarantine at Tor, followed by seven days in the supplementary station of Moses's wells, before being allowed to land their passengers in Suez; infected ships and, if cholera had broken out in the Hedjaz, all ships coming from that province had to perform 15 days' quarantine at El Wej.

The El Wej lazaret appears to have been already in existence as early as 1867, the year after the Constantinople Conference. Then, or later, a stone landing-pier was constructed there, some masonry buildings were put up, and condensers, to supply drinking-water, were installed on a floating barge or lighter. For ten years the lazaret continued to exist and to receive pilgrims. But in the interval it had come to be recognised that its site presented many and serious disadvantages. The harbour is an exceedingly small one; not more than two pilgrim ships of any size could lie there at a time. It is, moreover, dangerous of approach and exposed to frequent stormy winds, so that ships lying there had to keep their fires up ready to run to a safer harbour in case of necessity. British ship-masters protested strongly to the home Government against the continued use of this port as a quarantine station, and their assertions as to the dangers it presented were confirmed by independent reports made to the Admiralty by British cruisers in the Red Sea. The crisis came early in 1877, when one of the condensers which had been put up to supply the lazaret with drinking-water suddenly burst. The local water-supply was wholly inadequate and unsuited for the many pilgrims quarantined there and consequently the latter were transferred to the lazaret at El Tor which has ever since been the principal quarantine station for pilgrims returning northwards from the Hedjaz.

The abandonment of El Wej appears to have given rise to a very lively and vigorous controversy at the time. Captain (later Sir Richard) Burton, who was then inquiring into the mineral resources of that portion of Arabia, was requested by the British Government to report upon the suitability of El Wej as a port of quarantine. His opinions as to the relative advantages of that port and of El Tor (which were later repeated at length in his "Land of Midian Revisited") were expressed with characteristic freedom and force. No praise that could be given to El Wej appeared to him to be excessive, while, on the other hand, no condemnation was thought to be too strong for El Tor. The former was described as almost a terrestrial paradise, while the latter was characterised as a hotbed of fever, as "inhabited by a ring of thievish Syro-Egyptian traders, backed by a wretched wilderness, alternately swampy and sandy, and comfortless to an extent calculated to make the healthiest lose health." "Tor is, in fact," Captain Burton continued, "an excellent medium for focussing and for propagating contagious diseases; and its vicinity to Egypt, and consequently to Europe, suggests that it should at once be abolished."

The experience of 30 years has in no way confirmed the above apprehensions as to the unsuitability of Tor for a quarantine station for pilgrims or as to the likelihood of its tending to spread rather than to arrest epidemic disease. On the other hand, the lazaret of El Wej, once abandoned, could never be revived and nothing of it remains to-day but some crumbling ruins. There was, however, some years ago a movement on foot to build another lazaret or to repair the old one at El Wej. In the interval the frontier line between Egyptian territory and the province of the Hedjaz had been transferred from the neighbourhood of El Wej to that of Akaba on the Gulf of that name. This time, consequently, it was the Constantinople Board of Health that proposed to establish or to revive the lazaret there. This proposal was mainly the result of the great European epidemic of cholera in 1892–93. Plans for the new institution were prepared by the French contractor who had carried out the new works at the Camaran lazaret. They would have involved an outlay of £T.57,000. The project, which was sanctioned by an Iradé from the Sultan, was submitted to the International Sanitary Conference held in Paris in 1894. The proposed lazaret was to serve, as before, mainly for pilgrims returning from the Hedjaz. The conference, however, preferred to enlarge and to improve the El Tor lazaret for this purpose and the project was therefore rejected. The Turkish delegation, nevertheless, made a formal declaration to the Conference to the effect that the Constantinople Board of Health had definitely decided to build a lazaret at El Wej; that this new institution was to serve mainly for quarantining pilgrims going *to* the Hedjaz from the north, acting in this way an exactly similar rôle to the Camaran lazaret for pilgrims from the *south*; that it show this peculiarity most. In many cases the difference is startling; a sound inaudible or barely recognisable through the stethoscope is heard clearly and sharply by the naked ear. With louder bronchial sounds, especially with those of medium or low pitch, this difference in audibility is less or may be absent. But when the breath sounds are high and faint, as they often are at the beginning of pneumonic consolidation or in pleuritic effusion, the greater sensitiveness of the naked ear is obvious. The same is often true of amphoric breathing. For example, a man, aged 40 years, had fever, pain, and signs of fluid at the right base extending up to one inch below the angle of the scapula. With the stethoscope only absence of all breath sounds and a few fine râles were noted. But with the naked ear distinct amphoric breathing was heard by everyone who listened. The disease proved to be a large subphrenic abscess. Thus sounds best heard with the naked ear, whether pulmonary or cardiac, have in common high pitch, slight intensity, and a blowing or whizzing quality. What is the explanation of this fact? Most cardiac and many pulmonary sounds, such as the normal vesicular murmur and many râles, are best heard through the stethoscope. The reversal of this rule must be due either to the stethoscope transmitting certain types of sound less than others or to a selective action of the ear when in contact with the chest. Of the latter there is no evidence. On the other hand, it is well recognised in acoustics that high-pitched sounds are conducted along closed tubes less perfectly than are low-pitched ones and that the deadening effect is increased if the tubes have elastic walls. When the ear is applied directly to the chest sound is conveyed not only through the auditory meatus but also through the bones of the skull. With a flexible stethoscope this bone conduction is lost. For sounds of low pitch the intensification produced by the stethoscope more than compensates for the loss of bone conduction, but this is not true for faint sounds of high pitch.

---

[1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., X., and XI. were published in THE LANCET of April 27th (p. 1188), May 4th (p. 1251), 11th (p. 1317), and 18th (p. 1389), June 1st (p. 1518), 8th (p. 1607), 22nd (p. 1741), and 29th (p. 1810), and July 6th (p. 51), 13th (p. 114), and 20th (p. 190), 1907, respectively.

OLD BOTTLES AND THE PUBLIC HEALTH.

THE National Glass Bottle Workers' Trade Union sent last week a deputation to the President of the Local Government Board to call his attention to the indiscriminate manner in which old bottles are utilised to the danger of the public health. The spokesmen pointed out that these old bottles are frequently collected from ashpits and other receptacles for rubbish and sold for use after being imperfectly washed out with hot water. It was further stated that many of these bottles came from places where infectious disease existed and that they afforded a possible channel for its dissemination. It was urged that some system of sterilisation should be enforced in the case of such bottles before they were allowed to be sold and used again. Mr. Burns replied that he was in sympathy with the object of the deputation and promised to give his careful attention to the possibility of carrying out the practical suggestion placed before him. It is only necessary to read this protest to be in accord with it; there is no doubt that the practice complained of may well be a source of infection. We should like to think that no one purchasing such bottles would fill them with any liquid for public consumption without first satisfying himself of their cleanliness, but unfortunately our experience of other unchecked industrial processes, as witness the use of loathsome bed stuffing, does not make us too sanguine in the matter. It is surely not too much to demand that these old bottles should undergo a prolonged and efficient scalding either at the hands of the sellers or the buyers before being refilled and we trust that official action will be taken to secure this or some equally effectual precautionary measure. The National Glass Bottle Workers' Trade Union, even though its action was undertaken with one eye to its own interests and one eye to the public's, has done good service in calling attention to the matter.

THE COVENTRY AND WARWICKSHIRE HOSPITAL

WE have received a communication from the authorities of this hospital which appears to indicate that in the minds of medical men the institution has been confused with the Coventry Dispensary, concerning which there has been a good deal of discussion in our columns and elsewhere. The erroneous feeling has among other things caused doubt in the minds of young medical men who might otherwise have offered themselves as candidates for the resident appointments in the Coventry and Warwickshire Hospital. We beg to refer young medical men to the advertisement which will be found in another column of this issue for a junior house surgeon at this institution and we hope that the hospital will speedily receive suitable applications for the post. We must point out, however, that other circumstances may operate in making candidates for the post scarce, as many similar institutions are finding it difficult to secure resident officers. The reasons for the reluctance of young medical men to take small hospital appointments are not very obvious to us, for although the work is hard and the pay small the experience is extremely valuable. The reluctance, however, exists and may become a matter of serious importance to hospital authorities.

LIQUID PREDIGESTED FOODS.

THE Council on Pharmacy and Chemistry of the American Medical Association has recently published a report by a subcommittee which was appointed to examine the various "liquid foods," "medicinal foods," or "predigested foods," as found on the market in large numbers.[1] These foods are solutions containing as the essential constituents small amounts of protein substances and carbohydrates preserved by alcohol. In the preparation of such foods the protein substances should be converted into soluble peptones and proteoses by means of enzymes. The protein content of the various liquid foods examined ranged from 0·5 to more than 6 per cent. The carbohydrates present, amounting to from 0 55 to more than 15 per cent., included sucrose, maltose, glucose, invert sugar, and dextrin. The amount of alcohol varied from 12 to 19 per cent. Some of the foods contained a large proportion of glycerine. Their nutritive value depends on the amounts of protein and carbohydrate present, and these in many of the cases examined represented only one-third the calorific value of milk, while but a few possessed twice the calorific value of milk. The council has concluded that none of the commercial liquid medicinal foods examined contain sufficient food material to maintain normal nutrition. A man doing moderate work requires an amount of food capable of supplying energy equal to 3000 calories per day and in sickness about one-half this amount. The average daily dose of the "liquid foods" supplies only from 10 to 111 calories, based on the protein and carbohydrate present. It is calculated that to sustain the vitality of a patient during a serious illness about two litres of milk, giving 1430 calories, are required. Even if the alcohol is considered to have direct food value it would be necessary to administer from 700 to 1500 cubic centimetres of the "medicinal foods" to supply the same amount of energy. But in many cases the amount of alcohol exhibited by these quantities would keep the patient in a continuous state of alcoholic stupor. From these considerations it is clear that a patient would starve when these preparations are given in the doses that are recommended. Unless the advised daily dose of a

---

[1] Journal of the American Medical Association, May 11th, 107, p. 1612, and June 1st, p. 1866.

Lord Mayor of Manchester and the *Mayor of Salford* welcomed the members. Many purely technical papers were read. In the afternoon of July 23rd a reception and tea were given by Vice-Chancellor Hopkinson in the Whitworth Hall at the University. Professor R. B. Wild, the head of the pharmaceutical department of the medical school, said that the practice at the Victoria University was to teach pharmacy concurrently with medicine and chemistry. They aimed at following out the precept laid down by Mr. Tyrer, the President, and endeavoured to advance the cause of science by research. About 200 members attended from all parts of the country.

The Flannelette Danger.

Some correspondence has appeared in the papers on this question, and in a letter from Mr. S. Bradbury, F.C.S., of Ashton-on-Mersey, it is stated that at the inquest on the Rochdale burning case which occurred lately the mother said that the flannelette from which the child's night-dress had been made was sold to her as "non-flammable flannelette" by a travelling draper. A full investigation showed that it was of the ordinary kind. "A similar statement was made by a draper a couple of years ago and the man was traced and forced to publish an apology in the newspapers." Mr. Bradbury suggests that all flannelettes should be plainly stamped and the comparative safety or danger of the various sorts demonstrated. It is quite time that some steps should be taken to lessen the number of the children who are now burnt to death owing to wearing unsafe flannelette.

Novel Excuse for Assault.

A peculiar excuse was given by a Wigan man the other day when charged with being drunk and assaulting the police. The man said he had recently undergone an operation "and they reckon after a man undergoes an operation it takes effect on him." The excuse did not avail and he was fined *20s.* and costs.

Bradford Medical Men and the Watch Committee.

The Bradford watch committee recently advertised for police surgeons at fixed salaries to fill vacancies. But the local branch of the British Medical Association objected to the terms and all the candidates withdrew. A few days since a meeting of the branch was held at which a letter was received from the watch committee stating that somewhat lower fixed salaries would be offered and the usual medical fees allowed. This was considered satisfactory and it was agreed that the vacancies should be competed for.

July 30th.

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Water Supplies in Monmouthshire.

THE necessity for taking some steps to provide a proper supply of water for the increasing population in the mining districts of Monmouthshire has for some time been engaging the attention of the sanitary authorities of the county. There is little doubt as to the desirability of a general scheme being undertaken and it is anticipated that after the first few years such a scheme would be self-supporting. The initial expenditure, however, has to be met out of the general rates of the county and it has been difficult to persuade those who live in the purely rural districts that what is of advantage to a portion of the county is ultimately of advantage to the whole. There appears now to be some likelihood of an agreement being arrived at by the urban and rural sections of the county council. At a conference of sanitary authorities recently held at Newport resolutions were carried recommending the county council to introduce a Water Bill next session. The suggested provisions of the Bill would enable the costs of the Bill and the acquisition of lands to be a general county charge, the county to be recouped out of the profits of the undertaking when it reached a profit-earning stage. It is also proposed that the works should not be commenced until the county council has made such contracts with local authorities or water companies as would insure no loss to the county and that any water company taking water from the county council should be compelled under penalties to supply a given district under constant pressure. The county council has been advised by Mr. Baldwin Latham who recommended the construction of three reservoirs at an estimated cost of £730,000 which would supply 4,000,000 gallons daily.

Swansea Hospital.

Allegations of abuse of the Swansea Hospital have of late years been very frequently made. The question has been discussed by the board of management of the institution, and although there has been considerable difference of opinion as to the extent to which the abuse exists a majority of the board decided that it was desirable to make a systematic inquiry into the means of every patient. At the annual meeting of the subscribers to the institution held on July 19th this recommendation of the board of management was considered and its adoption was very strongly urged by Mr. W. F. Brook and Dr. H. A. Latimer, but it was rejected by a large majority, and a suggestion that inquiries should be made in doubtful cases only met with little support.

Important Decision as to Inferior Milk.

It has hitherto been considered a sufficient defence for a milkseller who is brought before a bench of magistrates for selling milk of an inferior quality to prove that the milk is poor as it comes from his cows. If a recent decision of the Bristol justices is upheld this defence will no longer be tenable. A milk dealer whose milk was found upon analysis to be deficient in milk fat proved to the satisfaction of the justices that his cows gave poor milk. He was, however, convicted, for the justices found that he was to blame. He had a good herd and knew the conditions of his farm and they considered that if he were to milk his cows at more equal periods, and to feed and house his cattle in a more husbandmanlike manner, there would be no difficulty in his getting milk of a proper standard.

North Devon Infirmary.

The annual meeting of the subscribers to the North Devon Infirmary, Barnstaple, was held on July 23rd under the presidency of Earl Fortescue. The medical report was satisfactory and the financial statement showed a favourable balance of £184. It was reported that the structural alterations in the building, which had recently been carried out at a cost of £4905, were now finished, and that the whole cost of the undertaking had been defrayed by a special appeal with the exception of £810 which had been allocated by the committee of the infirmary from the funds of the institution. After a considerable amount of discussion it was decided to alter the rules of the infirmary so as to exclude cases of enteric fever. This matter had been under consideration for several months and a special committee has been appointed to deal with the subject.

The Paignton Urban District Council and its Medical Officer of Health.

Some friction has recently arisen between the Paignton urban district council and its medical officer of health owing to the latter having opposed the application of the council at the recent Local Government Board inquiries respecting street improvements and the water distribution scheme respectively. At a meeting of the council held on July 15th the matter came under discussion and a motion was unanimously carried that the council should place on record its disapproval of the attitude taken by the medical officer of health at the two recent Local Government Board inquiries. Before the motion was put to the meeting the medical officer of health, who was present, protested that before this was done he should be allowed to reply but the chairman informed him that unless he intended to apologise for his action he could not be heard. The medical officer of health replied that he had no intention of apologising. It certainly seems somewhat arbitrary to condemn the action of any official in his presence without giving him an opportunity of reply.

British Dental Association.

The annual meeting of the Western Branch of the British Dental Association was held at Bath on July 26th and 27th, Mr. E. L. Dudley of Bath presiding. Dr. C. A. Hayman (Clifton) opened a discussion on Why do People Lose their Teeth at such an Early Age? Some interesting demonstrations were given by several of the members. The annual dinner took place on July 26th at the Empire Hotel. It was decided to hold the next annual meeting at Newquay.

Devon and Exeter Hospital.

On July 19th, in the presence of a large gathering, the new electrical department which has been added to the Devon and Exeter Hospital by Mrs. Sanders of Stoke Hill incalculable. Most of those who were associated with Dr. Nariman in the early days of his enterprise have passed away, but he is with us still, full of enthusiasm and vigour. This is a man whom Government and his own community should delight to honour and Hindus and Mahomedans to emulate." The enthusiasm of the *Times of India* is no doubt well founded. The Parsees of India, although a conservative and self-contained race, are full of energy and quick to recognise the material advantages of Western civilisation. In commerce they have no superiors; in the East there are few towns of importance where Parsees are not to be found ministering to the requirements of the less astute natives, and at the same time absorbing their spare cash. Parsee manners and customs were formerly open to criticism in many respects. It is satisfactory to find that reformation has now established itself upon such a secure foundation.

LEPROSY IN NEW SOUTH WALES.

THE annual report on leprosy in New South Wales, dealing with the events of the year 1906 and signed by Dr. J. Ashburton Thompson, President of the board of health, states that seven persons were admitted to the lazaret, one died, and four were discharged, one of whom was an Englishman recovered from the disease, and three were Chinese returned to their own country; on Dec. 31st, 1906, there were 20 persons remaining in the lazaret, of whom 10 were white and 10 were coloured. The lazaret is at Little Bay, near Sydney; the average daily number of patients for the year was 19·5 and the average cost per head was £79. The report, which fills 29 large pages of small print, with eight full-page plates of portraits, contains excellent clinical descriptions of all the new cases as well as of nine patients who had been in the lazaret for some years. In this latter group the first patient, who is now in the fourteenth year of his illness, had for one and a half years received intramuscular injections of one-fourth of a grain of perchloride of mercury dissolved in 20 minims of water, which were administered almost continuously for 65 weeks, once a week during some terms and twice a week during other terms. The disease, however, made uninterrupted progress. The second patient received for about four months bi-weekly injections identical with the preceding but the disease did not suffer any modification. The third patient began to take 30 minims of gurjun oil daily in July, 1904; this was gradually increased until he took 300 minims daily. In the middle of March, 1905, he began to take 45 minims of chaulmoogra oil daily in gelatin capsules, and the dose was increased until it reached 270 minims daily. The fourth patient was treated similarly. The fifth patient took free phosphorus and arsenic alternately during terms of about three weeks each. After four months of this treatment it was evident that the paralytic distortions of the fingers had diminished and that the fingers could be more freely and promptly moved by voluntary effort. Chaulmoogra oil was then substituted for the phosphorus and arsenic. The sixth patient was treated with the same drugs but without any evident result. The seventh patient, who was a female, 19 years of age and in the fifth year of illness, had made several attempts to take chaulmoogra oil but without success; the dose never exceeded 30 minims a day. In 1905 she suffered from a secondary infection with staphylococcus pyogenes aureus, attended by superficial ulcerations and serious ill-health. In the first week of 1906 she began to take ten grains of cuprol (a combination of copper with nucleinic acid) twice a day in cachets and a 10 per cent. ointment of cuprol and lanoline was applied to the ulcerations. At the end of August, when the cuprol was relinquished, she was treated with chaulmoogra oil and strychnine. The eighth patient was treated with gurjun oil, chaulmoogra oil, and strychnine. The ninth patient was treated with chaulmoogra oil and strychnine. Another patient, already referred to, after treatment with gurjun oil, chaulmoogra oil, and strychnine, recovered and was discharged from the lazaret.

EPIDEMIC CEREBRO-SPINAL FEVER.

THE gradual decline in the prevalence of epidemic cerebro-spinal fever still continues. In Scotland during the week ended July 27th there were seven deaths from this cause registered in Glasgow, three in Dundee, and one in Leith. In Glasgow the weekly report issued on July 26th showed that there were at that time 50 cases under treatment. In Belfast during the week ended July 27th there were 12 deaths registered as being due to this cause.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE council of the Metropolitan Hospital Sunday Fund at its meeting on August 1st, after considering the report of the committee of distribution, received a recommendation of the finance and general purposes committees to accept a proposition of the executors of the late Mr. George Herring, that a sum of £30,000 on account of the residuary bequest should be paid over. It is understood that this sum is about equivalent to one year's interest on the bequest, the size of which may be gauged by the fact that the same sum will be added to the collection for distribution yearly. Mr. Herring's magnificent liberality to the Metropolitan Hospital Sunday Fund will keep his name famous for ever among the charitable benefactors of the capital.

INDIAN HOSPITAL ASSISTANTS.

THE hospital assistants of India are a highly respectable and important body of public servants, numbering several thousands, who for a relatively small wage perform duties requiring both education and intelligence in a manner which is quite beyond praise. Though they belong to various nationalities and divers creeds, including Christianity, they have recently united to establish an All-India Hospital Assistants' Association and to issue a monthly journal which already bids fair to make its mark as a valuable and well-conducted publication, the contents consisting entirely of original matter written by the members themselves and not of transcriptions borrowed, with or without leave, from American and other medical papers. The association is under the patronage of several distinguished officers of the Indian Medical Service who desire to encourage originality of thought in their subordinates and have contributed funds to institute yearly prizes for original theses upon given subjects. This year the subject is "Plague," and Lieutenant-Colonel W. B. Bannerman, I.M.S., Major G. Lamb, I.M.S., and Major W. E. Jennings, I.M.S., have consented to act as judges. The journal for May opens with a paper on Dysentery, which was read before the Madras branch of the association by Mr. P. Vakulabaranam Chettiar. The writer modestly disclaims aiming at originality and calls his contribution a compilation, but nowadays those who produce absolutely original articles are not very numerous, so that he has plenty of company. "Many have written grand and eminent works on this subject," says Mr. Chettiar in his preface, "and I know it would be standing on slippery ground to attempt to write on the same, but I go with the satisfaction of having done something to relieve the suffering humanity, especially the Indians, and something in the shape of a very poor attempt to set forth my collected thoughts and experience in writing for the benefit of my professional brethren." The English language is truly full of pitfalls, but behalf of the Citizens' Association, also expressed appreciation of the manner in which the inquiry had been conducted. The chairman before closing the public portion of their work said he would like to say that it had been a great pleasure to the members of the Commission to hear the expressions of opinion from the chairman of the public health committee, Sir John Byers, Mr. Ferguson, and Mr. McGrath, and they were pleased to think that that opinion might possibly be shared by the people of Belfast. He earnestly hoped that the inquiry would prove to have been sufficiently useful to warrant the labour and the time which had been devoted to it. The inquiry, which has taken up 33 days, has now concluded so far as the taking of evidence which the Commissioners will consider, and it is expected that their report will be presented in the autumn. Already an immense amount of good has been effected by the very existence of this Health Commission, the public health committee having displayed an abnormal activity since its sittings began. When the report is tabled the public will have to decide what is to be done with its recommendations. In the meantime the Health Commission has had a wonderful educational effect.

Cerebro-spinal Fever in Belfast.

There is little change to report as to the prevalence of cerebro-spinal fever in Belfast. During the week ended July 20th there were seven cases as compared with eight in the previous week. Since the meeting of the public health committee on July 18th up to July 25th two cases of cerebro-spinal fever were notified to the health department, and during the week ended July 20th two deaths were registered as having been caused by this disease. At present there are in Purdysburn fever hospital 29 cases of cerebro-spinal fever.

Royal University of Ireland.

At a meeting of the Senate held on July 26th the following proposition was moved by Sir Christopher Nixon, seconded by the Rev. Dr. Hamilton, and passed unanimously :—

> That, having regard to the injurious impressions produced by the adverse comments on the working of this University as a teaching and examining body made in the report of the Royal Commission on University Education in Ireland (1903), and in the Royal Commission of Trinity College, Dublin, and the University of Dublin (1907), the Senate earnestly desires to bring under the notice of the Government the serious injury to higher education in Ireland which will result from any further postponement of the settlement of a question so vitally bound up with the intellectual and material progress of the country.

The following were named as a deputation to wait on the Chief Secretary in reference thereto: Lord Castletown, Sir Christopher Nixon, the Rev. William Delany, the Rev. Thomas Hamilton, Dr. John R. Leebody, Mr. Alexander Anderson, Lord Killanin, Dr. B. C. A. Windle, and the Right Rev. Monsignor Mannix.

July 30th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Liability of Medical Men.

IN the last number of THE LANCET I referred to a lega case possessing considerable interest for the medical profession—namely, an action brought by Mlle. Peyronette agains Dr. Cormon on account of bodily injury sustained by her in consequence of a method of treatment which he had adopted. The judgment of the court was delivered on July 20th and was in Dr. Cormon's favour. In arriving at this conclusion the court took into consideration the fact that mere imprudence, inattention, clumsiness, or neglect of the police regulations might be a professional misdemeanour (*délit*) in a medical practitioner, but that the bringing of a formal accusation against such practitioners for every act which might have a result detrimental to the patient would be going beyond the intention of the legislature and would imperil the very interests which the latter wished to preserve, for it would naturally have the effect of destroying all initiative and all free choice in the treatment of disease and in the performance of operations involving danger. In order to avoid extremes in either direction it must be recognised that the practical application of well-supported (*sérieuses*) medical theories, in accordance with scientific knowledge and the teaching of the schools, does not make the practitioner responsible to the law. On the other hand, inattention to the general rules of prudence and common sense which must be observed in all professions, gross neglect, or ignorance irreconcilable with the possession of a medical diploma, may make a practitioner responsible to the law and, in fact, ought to do so. Since, firstly, in the present case the charges brought against Dr. Cormon by the public prosecutor resolved themselves into a want of foresight in not attaching sufficient importance to the well-marked symptoms premonitory of superficial sloughing; secondly, since the treatment was on the whole in accordance with the principles accepted by the best medical and surgical authorities; and thirdly, since the patient under Dr. Cormon's treatment had recovered from an illness which threatened her life, the acts complained of would not justify the condemnation of the defendant. Dr. Cormon was therefore acquitted.

Hospital Dietaries.

At a meeting of the Hospitals' Medical Society held on July 5th M. Widal read the report of the committee to which had been assigned the duty of drawing up a salt-free dietary which it had been considered necessary to add to the other diets. The committee reported that it was impossible to lay down a hard-and-fast list of food (*menu défini*). The physician in charge of each case must decide upon the quantities of carbohydrate, protein, or fat which he should prescribe. All these various foodstuffs, however, will be prepared without salt.

Bequest by Professor Grancher.

In the obituary notice of Professor Grancher which appeared in THE LANCET of July 20th, p. 195, I mentioned that he had founded a society for the protection of children from tuberculosis. On the day after his funeral the committee of the society met at Madame Grancher's house and on the will being read it was found that the testator had left to the society a sum sufficient to produce an annual income of 20,000 francs. Madame Grancher has been made a member and vice-president of the committee. Dr. Roux, director of the Pasteur Institute, has accepted the position of president of the society.

July 29th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Suicides of Children.

Professor Eulenburg lately read a paper before the Verein für Schulgesundheitspflege (School Hygiene Society) on Suicides of School Children. These events are more frequent than is generally believed, as in Prussia from 1880 to 1903 there were no fewer than 1152 suicides of children attending schools, 340 of them being pupils in the higher schools and colleges and the remainder in public schools. In 423 cases punishment, non-success in classwork, and removal from school for misconduct were alleged to be the cause, so that about one-third of the suicides were attributed to reasons connected with the school. In about 10 per cent. mental and nervous troubles were present, while in 265 cases no cause could be found. In some cases the motives of the suicide were rather trivial, such as the refusal of the parents to allow certain games or recreations. The study of the works of some philosophers, especially of Schopenhauer and Nietsch, has induced some young men to take their lives, and in a number of cases love affairs have a preponderant influence in prompting the rash act. Professor Eulenburg, in concluding his address, a detailed report of which has appeared in the *Zeitschrift für Pädagogische Psychologie, Pathologie und Hygiene*, said that a good many suicides might be avoided if the individuality of the pupil were more considered by the school authorities and the parents.

Professional Unity.

A remarkable example of professional fellow feeling was lately given by the medical men of Wiesbaden. One of the medical officers to the Wiesbaden post office had during the late Parliamentary elections not only voted for the Socialist candidate but had also publicly spoken in his favour. He was therefore denounced and the director of the post office asked him as a Government medical officer for explanations which he refused to give, saying that he was not obliged to justify his political opinions. Notice was then accordingly given to him and the vacancy was advertised in the medical papers. The medical man in question therefore referred the outdoor exercise treatment of active insanity and those of the indoor rest treatment of it. He advocated an initial period of rest in bed for newly admitted patients of asylums. He had had much success from the outdoor rest treatment of active insanity in all newly admitted patients and in resident patients during relapses or phases of active insanity, including the difficult and dangerous cases. At Ayr there were both isolation verandahs and association verandahs. He contended that the open-air rest treatment of active insanity secured the advantages without the disadvantages of the outdoor exercise and indoor rest systems combined. The idea had originated from the open air treatment of the tuberculous insane, and it not only quickly improved the general condition and appearance but the regularity of the bowels, so that laxatives were but little needed.

The paper was very fully discussed by the PRESIDENT, Dr. D. YELLOWLEES, Dr. W. J. MACKEOWN, Dr. ALBERT WILSON, Dr. THOMPSON, Dr. CLOUSTON, Dr. E. GOODALL, Dr. STODDART, and Dr. C. HUBERT BOND, and Dr. EASTERBROOK replied.

In the evening the members and guests dined in the Whitehall Rooms, Hôtel Métropole, under the presidency of Dr. MACDONALD, when there was a large and distinguished company. Among the guests were Lord Digby, the Bishop of Salisbury, the Ven. Leslie Dundas, Sir James Crichton-Browne, Dr. D. Nicolson, Sir Victor Horsley, Sir John B. Tuke, M.P., Sir Henry Craik, M.P., Sir R. Douglas Powell, Sir Patrick Manson, Mr. Thomas Hardy, Professor T. Clifford Allbutt, Professor D. Ferrier, Colonel Mount Batten, Dr. John Macpherson, Mr. J. Bland-Sutton, Dr. H. W. Hurd (Baltimore), and Lieutenant-Colonel Symes.

After the usual loyal toasts had been warmly pledged, Dr. CLOUSTON proposed "The Houses of Parliament," and pleaded for a system of pensions for asylum medical officers as in the case of other civil servants. The toast was responded to by Lord DIGBY and Colonel WILLIAMS, M.P. "The Medico-Psychological Association" was proposed by Sir VICTOR HORSLEY who, in paying a high tribute to the pioneer work done by the association, referred to the recent occasion on which he acted as spokesman of a medical deputation to a Minister, when he was told that his request was tendered in a peremptory manner. He justified his action and contended that such was shown to be necessary by the history of similar efforts. The PRESIDENT replied. "Science and Sister Societies" was eloquently proposed by Sir JAMES CRICHTON-BROWNE. He said that the association might well do honour to science, for during his 45 years' membership it had advanced in usefulness just in proportion as it had become scientific. Indeed, in the inmates of asylums one could sometimes see the lurid reflex of great and glowing orbs of science and the hallucinatory images kept pace with science itself. Professor CLIFFORD ALLBUTT replied, and after a graceful tribute to the work being accomplished by the association he lamented the fact that there was no Ministry of Public Health, despite the enormous importance of the subject to the community. He pleaded for a proper correlation of the various agencies of the kind to be concentrated in a definite Government department. "The Visitors" was proposed by Dr. URQUHART, and responded to by Sir RICHARD DOUGLAS POWELL, Dr. MACPHERSON, and Dr. HURD (Baltimore), the last named gentleman acknowledging the indebtedness which American psychologists were under to the members of that association. "The President" was proposed in highly eulogistic terms by Dr. NICOLSON and Dr. MACDONALD replied.

The meeting was resumed on Friday, when Dr. CLOUSTON introduced a discussion on "Psychiatry as a part of Public Medicine." He urged that preventive psychiatry should be made a part of general hygiene and suggested that the Local Government Board should extend its sphere to include that, the speech constituting a strong plea for coöperation for the good of the community. The discussion revealed a unanimity of view as to the importance of the subject but differences as to the remedying of the defect.

At the afternoon sitting two remarkable papers were read, one by Dr. WILSON (a clinical demonstration) on "The Psychology of Crime," and the other by Dr. W. FORD ROBERTSON and Dr. G. DOUGLAS MCRAE on "Observations on the Treatment of General Paralysis and Tabes Dorsalis by Vaccines and Antisera." Dr. Wilson exhibited a number of notorious criminals who under the agency of the Salvation Army had become reformed. He traced their histories and achievements and dealt with the whole subject in a very thorough manner. After a few words of appreciation from the PRESIDENT, Dr. SAVAGE, and Dr. CLOUSTON, the discussion was by agreement deferred until the November meeting of the association. Dr. Ford Robertson's and Dr. McRae's contribution, which was illustrated with microscopic slides, was discussed by the PRESIDENT, Dr. CLOUSTON, Dr. MICKLE, Dr. GOODALL, Dr. DIXON, Dr. ROWS, Dr. ORR, and Dr. MERCIER, and Dr. FORD ROBERTSON and Dr. MCRAE replied. In closing the meeting the PRESIDENT said the importance of the last communication was equal to that of any contribution which had ever been brought before the association.

OPENING OF THE NEW PREMISES OF THE CITY OF LONDON LYING-IN HOSPITAL.

THE new premises of this hospital were recently opened by Her Royal Highness the Princess Christian of Schleswig-Holstein in the presence of a representative company. The charity was founded in 1750 and the necessity for rebuilding the hospital arose out of the construction of a tube railway station opposite. The construction of such stations, as pointed out by THE LANCET[1] prior to the opening of the Central London Railway, must inevitably be attended with damage to adjacent property when the subsoil is of a porous nature or contains much water, and our foreboding was justified.

From its position the patients of the hospital are drawn from the purlieus of St. Luke's, Hoxton, Clerkenwell, Shoreditch, and Bethnal Green, perhaps the poorest and most densely crowded district in London. During the past ten years—1897 to 1906—5903 women were delivered in the hospital, giving birth to 5976 infants, 142 of whom were twins while three were triplets. The average weight of each child at birth was between 7 and 8 pounds; only one child reached 12 pounds, weighing 12 pounds 2 ounces. Of outdoor patients during the same period delivered by the hospital midwives at the patients' homes, 21,114 gave birth to 21,394 infants, of whom 272 were twins, 12 were triplets, and four were the result of one birth. The physique of the patients generally is very poor.

The work of rebuilding cost £36,000 and has absorbed all available funds, leaving the management encumbered with a debt of £29,000, but the money has been thoroughly well spent as the following detailed description of the new buildings will show. The exterior of the new building is an unassuming elevation of red brick and terra-cotta; though occupying a prominent position at the north-west corner of the City-road and Old-street it is dwarfed by being placed between the huge blocks of the Leysian Mission and St. Luke's Hospital. The architect, Mr. Collins, R.I.B.A., is to be complimented in that he has successfully devoted his talent and the money placed at his disposal to secure efficiency rather than an imposing elevation and elaborate architectural details.

On plan each block of wards radiates from a common centre formed by the administrative block to which they are connected by short corridors; by this arrangement the maximum amount of light and air is obtained and each block isolated; indeed, each ward may be said to be the same, there being a well-ventilated space between the ceiling of one and the concrete floor of the ward above. There are eight ordinary and two labour or operating wards, an isolation ward with offices, only accessible by crossing an open space on the roof, also a small detached ward for cases of acute mania, which is especially provided with means for air flushing. In addition there are bathrooms, waiting- and consulting-rooms, besides the administrative block. Every new hospital adds something in advance of its predecessor in the direction of aseptic construction and the present instance forms no exception. Simplicity of detail and the absence of facilities for the lodgment of dust predominate; the doors, formed of one solid piece of teak, are without joints or mouldings. The ceilings, walls, and floors present one continuous unbroken surface and all angles are rounded. The steam coils swing out from the walls for cleaning. There is a specially constructed external aseptic shoot for soiled linen. Incinerator, steriliser for clothes, &c., all are there. The lift, which is electric and automatic, is capable of taking a bed. There are the usual ventilated cupboards for the satisfactory, believes that the subscribers should take an early opportunity of having an inquiry into the management of the Macedon sanatorium and of the Melbourne office."

June 29th.

Obituary.

JOHN SHERWOOD STOCKER, M.D. LOND., M.R.C.P. LOND., M.R.C.S. ENG.

John Sherwood Stocker, who died on July 18th after a prolonged illness, was born on April 9th, 1826. His father was Richard Stocker of Great Cumberland-place, a well-known West-End practitioner; his grandfather (whose name was also Richard) was for 40 years apothecary at Guy's Hospital, combining with that office further duties analogous to those at present fulfilled by a house physician and a dean of the medical school—there was less division of labour in those days; and his great-grandfather, John Stocker, was a general medical practitioner at Fareham in Hampshire. Thus it will be seen that Dr. Stocker came of a good old medical stock. He was educated at King's College School and Guy's Hospital and became qualified in 1849. In 1851 he took the degree of M.B. (with high honours both in surgery and medicine) at the University of London and two years later obtained the degree of M.D. He also studied at the University of Paris and was there during the Revolution of 1847. He was for some time assistant physician to the Samaritan Free Hospital for Women, and he was also for many years physician and subsequently consulting physician on the staff of the Western General Dispensary. He was a prominent figure at the Society of Apothecaries, being a member of the Court of Examiners from 1884 to 1892, junior warden in 1897, senior warden in 1898, and Master in 1899. A colleague on the Court of Examiners states that he was an excellent chairman, devoted to his work at the Hall, and spared no pains to foster the friendly feeling which always existed between the examiners. There was general regret when he left the Court of Examiners to become a member of the Court of Assistants. Until his retirement from practice Dr. Stocker resided at Montagu-square.

A consulting surgeon at Guy's, one of his few surviving contemporaries at that hospital, writes of the high esteem, popularity, and affection in which Dr. Stocker was held by all who were associated with him. His generosity was well known to all; not less conspicuous was his cheery, bright, and happy disposition, and simplicity and sincerity were marked features of his character. A London graduate who was intimate with him, writes: "His leading professional trait, in my opinion, was his wonderful aptitude at diagnosis; I often marvelled at the facility with which he could make a diagnosis by mere scrutiny and without making any further physical examination." Dr. Stocker was twice married—first to Mary Ann, daughter of Mr. Richard Worlidge Southby, and secondly to Charlotte Frances, sister of the Right Hon. Sir Joseph Cockfield Dimsdale, Bart. He was a widower at the time of his death and leaves two sons.

A RUSSIAN CANCER COMMITTEE.—The Medical Council of the Ministry of the Interior has formed a special committee, with V. V. Podvysotsk, director of the Institute of Experimental Medicine, as president, to study the question of establishing a committee in Russia for the investigation of cancer.

PROPOSED TESTIMONIAL TO DR. J. MILSON RHODES.—A public meeting has been held at Didsbury at which it was resolved to present a memorial to Dr. Milson Rhodes for his services in freely helping the poor, the insane, the epileptic, the suffering, and the friendless. It has occurred to the editors of the *Poor-law Officers' Journal* that many people in a much larger area than Didsbury would like to be associated with the testimonial which it is proposed should take the form of a cheque with an address. They will accordingly have pleasure in receiving any subscriptions that may be forwarded from those directly connected with the Poor-law and in sending these in due course to the committee of the fund, which is composed of well-known Manchester public men. Any subscriptions that may be sent will be announced in full in the columns of the *Poor-law Officers' Journal*, 18 and 19, Whitefriars street, Fleet-street, London, E.C., and the editors have started the movement with a subscription of five guineas.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT EXETER.

THE seventy-fifth annual meeting of the British Medical Association opened at Exeter on Saturday, July 27th, with the annual general meeting which was held at 9.30 A.M. in the Royal Public Rooms. The Association last met in Exeter in 1842, the then President being Mr. John Haddy James, surgeon to the Royal Devon and Exeter Hospital. This year the President is Dr. Henry Davy, physician to the Royal Devon and Exeter Hospital.

Exeter is one of the few English towns which can trace a continuity of civic life from Roman times. It was the Isca of Roman Britain and later was divided between the remnant of the Britons and the invading Saxons. The city has undergone some 14 sieges, the last being in 1646. It is therefore a place of great historical interest and retains a fair number of ancient buildings, while having no manufactories of importance it is clean and bright. There is a pleasant public garden, Northernhay, which was made public so long ago as 1612. It lies at the foot of the mound (Rougemount) on which the ancient castle stood, and occupies the site of the old north ditch which was filled in about 1607. The Cathedral is, of course, one of the most beautiful in England. It is of medical interest to remember that Exeter formerly possessed a leper hospital which stood outside the south gate and was dedicated to St. Mary Magdalen. Its inhabitants were cared for, if not medically treated, by the Grey Friars who arrived about 1250. Coming down to more modern times, the Royal Devon and Exeter Hospital, founded in 1741, was one of the earliest county hospitals in England, while the West of England Eye Infirmary was the second institution of the kind in England, Moorfields being the first. An Exeter surgeon named James was the second English operator to tie the abdominal aorta.

It was evident on Sunday that the atmosphere of medicine had affected the Cathedral, for both preachers discoursed upon medical matters. In the morning the Bishop of Crediton, taking for his text I. Cor. xii. 9, "The gifts of healing by the same spirit," said that men were too much inclined to call that which they did not understand supernatural. But the natural and the supernatural were really one. All our Blessed Lord's miracles of healing were done in accordance with the laws of nature. Yesterday Marconi laid hold of a law by which he was able to perform what appeared to many to be the most wonderful miracle of modern times; and if a man could thus control nature, it was conceivable that the Lord Christ Jesus did control it also, acting in accordance with those laws and working with a knowledge of spiritual causation. A man surely would have more presumption than wisdom who would venture to assert that our Lord's miracles of healing could not have taken place, so much were they encouraged by a fuller knowledge, while humbled by it. It would not do in the face of the discovery of the x rays to be dogmatic in regard to what was possible or impossible in the realms of fact. Great men of science who lived close to nature were speaking with exceeding modesty, and nature was ever revealing her choicest secrets to such as were in sympathy with her and who reverenced her God. In the evening Prebendary Dangar preached upon research, saying that the spirit of research was sanctified and elevated into a holy avocation in things pertaining to the body as well as to the soul.

The people of the city manifested an obvious interest in the proceedings. Crowds turned out to view the civic and

Mr. O. L. Smiles, and Dr. Frederick Taylor. The proceedings commenced with a service in the chapel, in the course of which the Head Master requested Mr. Morris, treasurer of the College and an old Epsomian, to unveil the window.

Before doing this Mr. MORRIS addressed the congregation as follows: "Founder's day which annually brings us here together, is this year a special occasion, because of the Jubilee Memorial window which is now about to be unveiled, and which immediately afterwards will be dedicated with all the sacred ceremony of a religious rite. The thought of celebrating the Jubilee of the College by beautifying the chancel of our chapel by this new East window was originated, I believe, by Mrs. Smith-Pearse, and certainly she has bestowed a great deal of time and labour in accomplishing her object. The idea was that the window should be the product of an appeal made chiefly, if not exclusively, to old Epsomians, and this idea has been fairly well realized. The window itself will, I think, be regarded by all as a tribute worthy of the occasion, as a great ornament to the chapel, and as a pictorial expression of the veneration and reverence suitable to the solemnity and sanctity of a House devoted to Divine service. The window and the sentiment which it embodies would have delighted the spirit of the humane and warm-hearted founder of the College. As a work of art, in its conception and execution, it cannot fail to be a permanent source of gratification and satisfaction to the donors; whilst it will recall to the minds of those who examine it, and think upon it, examples in life of self-sacrifice and courage, of benevolence and fortitude, of charity and loving-kindness. May we not expect that this beautiful window will be an incentive to, and a forerunner of, the reconstruction of the body of this chapel in a size of greater dimensions, and in a style consistent with the eastern or chancel end of the chapel. May we not hope that present and future Epsomians looking upon this window will see there a witness of the fact that the old Epsomians of the pre-jubilee period came back to their *alma mater*, as it were, to erect it as an emblem of the love and gratitude they carry in their hearts towards their old school. May we not also express the hope that those here now and those who will follow in the times to come will find in the subjects which are portrayed in this window promptings to guide them rightly in their careers in life. In the words of our president, Earl Rosebery, which he used in an address delivered several years ago when referring to the thousands of emigrants who annually leave our shores to settle in different parts of the world, may we not express the hope that those who now and in the future come to study in this school, and to worship in this chapel with this superb window in front of them may pass forth from here as a broad and bright and beneficent river of life, fertilising as the Nile, beloved as the Ganges, and sacred as the Jordan; and that like the fabled fountain Arethusa, which passing under the sea from Greece into Sicily yet retained its original source in Arcadia, so the old Epsomians of the future may be able to trace back the source of their useful and honourable careers to the impressions they received at school, and to the inspirations they derived from the contemplation of such actions and motives as are illuminated in the window which I will now unveil to you."

After the unveiling of the window the Dean of Winchester dedicated it "To the honour and glory of Almighty God and in gratitude for all His mercies vouchsafed to this school during the 50 years since it was founded......," in accordance with the form of service fixed for the occasion.

The window has been erected at a cost of £700 by contributions from old Epsomians and other friends of the school in commemoration of the jubilee of the opening of the College which was celebrated two years ago. Mr. J. B. Lamb, the secretary of the College, has kindly given us the following full description of it:—

> The window measures 21 feet 6 inches in height and 19 feet 6 inches in width, and has been made by the firm of Messrs. Powell and Sons, of Whitefriars, under the supervision of Mr. James Powell who arranged the design. General satisfaction was expressed by the numerous visitors who inspected the window, and it was felt that the artists had dealt very satisfactorily with a difficulty resulting from the deep colour of the brickwork inside the chapel, this heaviness having been in a great measure overcome by concentrating the varying tints of red in the centre of the window, retaining the lighter colours for the outside parts. The central subject is the divine love of man as proved by the Atonement, Christ being represented as hanging on the cross, whilst the distant walls and towers of Jerusalem, lighted by the deep rays of the setting sun, are symbolical of His death. On the left hand side of the main subject are figures of Melchizedek, Solomon, Noah, Daniel, and Job, and in front there is a group of boys, including Joseph as a shepherd boy, Isaac carrying the wood for the sacrifice, and the boy Samuel. On the opposite side are figures of St. Stephen, St. George, St. Swithun, Bishop of Winchester, St. Edmund, King and Martyr, and St. Alban; and in front there is another group of boys, including St. Pancras, St. Cuthbert as a shepherd boy, and a kneeling figure of St. Prisca. St. John is shown at the foot of the cross about to lead away the Blessed Virgin, and behind are groups of Roman soldiers.
>
> One interesting and uncommon feature is specially worthy of notice—namely, the eight seraph angels shown on winged wheels, two above and six below the cross and crown in the centre quatrefoil, the idea for these having been taken by Mr. Powell from the fourteenth century glass in Hitcham Church, Buckinghamshire. In the bases of the three central lights the conquered dragon is represented, symbolical of the victory of the cross of Christ over sin. In the outside lights there are single figures of healers from the Bible, on the left being Moses and Elijah, representatives of the Old Testament, and on the right St. Luke and St. Paul, representatives of the New Testament. Moses is shown as holding up the brazen serpent for the healing of the Israelites, whilst above is shown the angel in the burning bush. Elijah is shown with the widow's son whom he restored to life, and above there is the angel that directed the ravens to bring him sustenance. St. Luke, the "Beloved Physician," is shown holding the rod of Æsculapius in his hand, his emblem, the bull, being behind him, whilst above is the angel that appeared to Christ in the garden to strengthen Him during His agony; over the figure of St. Paul is to be seen the angel who showed to St. John the river and trees of life for the healing of the nations. In the Predella subjects to the four side lights are shown two incidents from the Old Testament referring to the boyhood of David, the ancestor of Christ, and two from the New Testament relating to the boyhood of Christ Himself. These four subjects have been wisely selected for the purpose of keeping before school boys the value of practical virtues, those chosen being "Courage," represented by David killing the lion which attacked his father's sheep; "Brotherly Kindness," shown by the love of Jonathan for David; "Wisdom," the incident selected being Christ in the Temple in the midst of the doctors; and "Obedience," Christ being shown in the carpenter's shop at Nazareth, thus ennobling manual work. In the tracery lights over the four side lights are coats of arms, the four principal ones being those of the King as patron of the College, of the Bishop of Winchester as Visitor, of the Earl of Rosebery as President, and of Mr. Propert as Founder. The smaller coats of arms, representing the school houses, are those of the late Dr. William Carr, who was a zealous honorary local secretary (Carr house); of the late Mr. Robert Forest, who was a generous benefactor (Forest house); of the late Earl Granville, who for many years held the office of President (Granville house); of the late Sir Erasmus Wilson, who presented to the College the head-master's house (Wilson house); of the late Sir Joseph Fayrer, who was for many years chairman of the Council (Fayrer house); and of Sir Constantine Holman, M.D. St. And., who held the office of treasurer for 19 years and is a Vice-President of the College (Holman house).

At the distribution of the prizes the head-master gave his customary report on the working of the school year and drew attention to the honours which had been won directly from the school since the last Founder's day. Among these are an open junior studentship in classics at Christchurch College, Oxford; an open exhibition in natural science at Clare College, Cambridge; and open scholarships at St. Mary's and Charing Cross Hospitals. In distributing the chief prizes the Dean of Winchester selected as the subject of his address to the boys the importance of cultivating habits of observation and imagination and of training the mind, reminding the boys that whilst few persons had ability all could with perseverance acquire a trained mind. His impressive address was greatly appreciated and was warmly commended by the treasurer who moved a vote of thanks to the speaker. During the afternoon the cadet corps paraded and there was a gymnastic display in the college grounds. Plans of the important alterations and additions to the college buildings which are about to be commenced were on view, the actual places where the buildings are to be erected being pegged out with flags. These extensions comprise a new science block containing physical and biological laboratories and class rooms, a lecture room, three more general class rooms, and a day-boys' common room; also further lavatory and water-closet accommodation; with covered ways between the present covered way and the lavatory block, &c., and between the present chemistry block and the new science block.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary Comitia was held on July 25th, Sir RICHARD DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

The PRESIDENT announced that the Bradshaw lecture would be delivered on Nov. 5th by Sir James Barr on Pleural Effusions and their Treatment and the FitzPatrick lectures on Nov. 7th and 12th by Dr. P. H. Pye-Smith on the History of Medicine.

The following nominations to lectureships during 1908 and by the Bishop, his chaplain bearing the pastoral staff, and the dean with the other clergy. Next came the medical men in a great diversity of gowns lending the colour to the proceedings. In the Cathedral nave was a large congregation, including the Mayor and the corporation who, with the other civic authorities, had gone in procession from the Guildhall. The sermon preached by the Bishop of the diocese was altogether admirable. His text was, "They that are whole need not a physician, but they that are sick," and on this theme he delivered a clear, well-reasoned discourse on the relative duties of the priest as physician of the soul and the medical man as physician of the body, and how in many cases their fields of action overlapped.

Tuesday evening was devoted to the introduction of foreign guests and colonial delegates and to the address of the President. The proceedings were held in the theatre, the stage of which was occupied by the officials of the Association and various members in academical dress, the doctors wearing their scarlet. The following were the foreign guests who had been invited, some of whom were unavoidably prevented from attending. Those present were introduced by Mr. Russell Coombe. Professor Dr. Paul Strassmann (Berlin), Professor Onodi (Budapest), Professor Stephane Leduc (Nantes), Professor Dr. Wertheim Salomonson (Amsterdam), Dr. Bonnefoy (Cannes), Dr. Chevalier Jackson (Pittsburg), Dr. E. Landolt (Paris), Dr. B. H. Buxton (Cornell), Dr. H. M. Fish (Chicago), Dr. E. E. Southard (Harvard, Danvers), Professor McCrae (Baltimore), Professor W. Northrupp (New York), Dr. M. S. Birkett (Montreal), Dr. Eretch (Brussels), and Dr. W. Oldright (Toronto).

After these came the colonial delegates, of whom the following is a full list:—Cape of Good Hope: Eastern Provinces, Dr. F. T. Waldron; Western Provinces, Dr. A. Jasper Anderson. Colombo and Ceylon Branch: Dr. F. Grenier and Dr. Fernando. Gibraltar Branch: Dr. A. W. W. Dowding. Griqualand West: Dr. Arnold H. Watkins. Melbourne: Dr. R. R. Stawell. Montreal: Dr. H. S. Birkett. Natal: Dr. W. R. Strapp. New Zealand: Dr. Albert Martin. St. John's, New Brunswick: Dr. A. B. Atherton. South Australia: Dr. H. Swift. South Indian and Madras Branch: Major F. J. Crawford, I.M.S., and Captain F. S. Ross, I.M.S. Sydney and New South Wales Branch: Sir Philip Sydney Jones, Dr. Ralph Worrall, and Dr. C. P. B. Clubbe. Toronto: Dr. Reeve, Professor Irving Cameron, and Dr. F. N. G. Starr. West Australian Branch: Dr. T. L. Anderson.

Dr. Deas then introduced the President, Dr. Davy, to the meeting, and the latter after a few words of thanks said that it was his very pleasant duty to announce that the Middlemore prize, consisting of an illuminated address and a cheque for £50, had been awarded to Mr. Sydney Stephenson for his essay on Ophthalmia Neonatorum with Special Reference to Causation and Prevention. Dr. Deas then presented the President, on behalf of the South-Western branch of the Association, with an heraldic jewel hanging from a Crowned X (the old Exeter mint mark) in commemoration of his call to his high office, after which Dr. Davy delivered his address, an abstract of which is published at p. 273. At the conclusion of the address a vote of thanks was moved by Professor Osler and seconded by Sir Philip Sydney Jones. Dr. Davy replied and the proceedings terminated.

We wish to express our warm thanks to Mr. Guy Elliston, the general secretary of the Association, and to the local officials, organising secretaries, and others for the great courtesy and assistance afforded in various ways to the representatives of THE LANCET.

THE SECTIONS.

MEDICINE.

WEDNESDAY, JULY 31ST.

Dr. WILLIAM GORDON (Exeter), the President of the section, made some brief introductory remarks, welcoming the members of the section to Exeter, and expressing his appreciation of the honour of being selected as President.

A discussion followed on

The Indications for Operation in Cases of Intracranial Tumour.

Dr. J. S. RISIEN RUSSELL (London), in introducing the discussion, said that there seemed to be a general impression that but little good could be hoped for from surgery in the treatment of intracranial tumour. This was an erroneous view which he hoped this discussion would dispel. If benefit did not result from surgical measures it was in most instances because the cases were not diagnosed early enough or not sent to the surgeon early in the course of the case when the growth was small. In making an appeal for a more careful consideration of the question he had no desire for intemperance in regard to the employment of operations on the brain but simply for less scepticism in regard to the value of such measures. He then proceeded to discuss the importance of diagnosis, in which connexion he called attention to the possibility of confusing cerebral tumour with disseminate sclerosis, general paralysis of the insane, cerebral thrombosis, and certain other affections, including hysteria, which in his experience had been operated upon in mistake for intracranial tumour, and he emphasised the important points which serve to distinguish these affections from cerebral tumour. In dealing with the conditions under which operation is to be recommended he drew a distinction between cases in which it was advocated with a view to effect cure and those in which it was undertaken merely as a palliative measure. Before advising operation in the first class of cases it was essential that the exact localisation of the tumour should be determined, and this not only in so far as to be able to say that it occupied the brain, as opposed to the cerebellum or pons, but also which cerebral or cerebellar hemisphere was involved and in what part of the hemisphere it would be found. Tumours situated near the surface of the cerebrum and those occupying one lateral lobe of the cerebellum or the lateral recess were the most favourable for operation, while those in the mesencephalon were inaccessible and those in the deeper parts of the cerebral hemispheres too remote to permit of a reasonable chance of cure. The probable nature of the growth had an important bearing on the question under consideration owing to the possibility of recurrence in the case of a malignant growth, which naturally offered much less chance of cure than when the tumour was benign. The prognosis was also less favourable in cases in which diffuse or multiple tumours were present than when the neoplasm was circumscribed or single. In referring to syphilitic tumours, he laid stress upon the fact that surgical intervention was necessary in a considerable proportion of these cases and his experience had proved that it was useless to waste valuable time in pushing antisyphilitic treatment when the symptoms were not yielding to mercury and iodide of potassium. Another important consideration was the degree of risk to life from the operation and its immediate effects, with regard to which he hoped to hear the opinions of some of the surgeons who were to take part in the discussion. His own opinion was that where other considerations justified the belief that a tumour which had been diagnosed and accurately localised could be successfully reached and removed by the surgeon the risk to life ought not to deter the physician from recommending the operation. The amount of permanent defect likely to result from the operation should also be taken into consideration. In cases where paralysis was to be expected he would have no hesitation in advising operation, as death was the only alternative; but it was a much more difficult problem when permanent aphasia was likely to result. The majority of people would probably hesitate, if indeed they could ever bring themselves to accept an alternative to which death seemed almost preferable. With regard to palliative operations, there could be no question as to the beneficial effects of trephining for the relief of abnormal intracranial pressure without removal of the whole or part help from relatives and is endeavouring to obtain boarders. Two children, aged nine and seven years. Voted £5.

Widow, aged 67 years, of M.R.C.S.Eng. who was a surgeon in the Indian Emigration Service. No income, no children. Voted £12.

Widow, aged 51 years, of M.R.C.S., L.S.A. who practised in Lincolnshire and London. No income; a little assistance from a struggling son-in-law; children unable to help. Voted £12

Widow, aged 62 years, of L.S.A. who practised in Derbyshire. No income, dependent on a son earning a small weekly wage. Health very indifferent. Relieved six times, £66. Voted £12.

Widow, aged 56 years, of L.R.C.P. Lond. who practised in Wales. Income £13 a year and receives a little help from a Masonic charity. Relieved twice, £10 Voted £5.

Widow, aged 62 years, of M.R.C.S. who practised in Liverpool. Earns a few shillings a week by giving music lessons. Relieved nine times, £77. Voted £5.

Daughter, aged 26 years, of late M.D. who practised in Middlesex. Physically and mentally unable to learn a living. Relieved twice, £15. Voted £5.

Daughter, aged 57 years, of late M.R.C.S., L.S.A. who practised in Hants. Income £15 a year and receives a little help from brothers. Failing eyesight interferes with needlework, by which applicant has supplemented her small means. Relieved twice, £12. Voted £5.

Daughter, aged 37 years, of M.D. who practised in Gloucestershire. Has been a cripple for many years and recently has been compelled to incur some extra and quite unavoidable expenses. Relieved twice, £12. Voted £5.

Daughter, aged 39 years, of late M.D. Edin. who practised in London. No income; is a governess but finds increasing difficulty in obtaining posts Relieved six times, £25. Voted £5.

Daughter, aged 37 years, of late L.F.P.S. Glasg. who was a surgeon in the Royal Navy. Is a nurse but has been incapacitated for nearly two years and for several months will only be allowed slight and occasional occupation. Relieved once, £12. Voted £5.

Widow, aged 53 years, of M.B. Cantab. who practised in London. No income; endeavours to support herself by washing, needlework, &c. Slight help from children, three of whom are in service. Relieved four times. £53 Voted £12.

Daughter, aged 55 years, of late M.R.C.S., L.S.A. who practised in Buckinghamshire. Income £5 a year; does a little teaching but earnings decrease each year. Relieved six times, £58. Voted £5.

Widow, aged 68 years, of M.R.C.S., L.R.C.P. who practised in London. No income; supports herself as a working housekeeper, but earnings are insufficient to cover unavoidable expenses for herself and two children at institutions. Voted £5.

Widow, aged 67 years, of L.S.A. who practised in Yorkshire. No income; no children; unable to get work; health indifferent. Relieved once, £5. Voted £5.

Widow, aged 55 years, of L.R.C.P., L.R.C.S. Edin. who practised in Staffordshire. Income less than £10 a year; slight help from a brother-in-law. Two children, aged 16 and 12 years. Relieved twice, £20. Voted £10.

Widow, aged 76 years, of M.R.C.S., L.S.A. who practised in Buckinghamshire. Has a small income, but insufficient for the maintenance of herself and four children, three of whom are deaf and dumb and one epileptic also. Relieved five times, £40. *Voted £5*

Widow, aged 60 years, of L.F.P.S. Glasg. who practised in Glasgow. Only income £10 a year from a charity. No children; broken down in health. Relieved five times, £50 Voted £10

Widow, aged 67 years, of M.D. Aberd., M.R.C.S. who practised in London. No income; slight help from children. Relieved six times, £79. Voted £12.

Widow, aged 61 years, of L.R.C.P., L.F.P.S. Glasg. who practised in Sunderland. Only income a small annuity. Children unable to help. Relieved ten times. £106. Voted £10.

Widow, aged 63 years, of L.R.C.S., L.R.C.P. Edin. who practised in London. No income; dependent on earnings from needlework. Relieved once, £10. Voted £10

Daughter, aged 61 years, of late L.S.A. who practised in Sunderland. Has a small annuity and is obliged to help an invalid sister. Relieved eight times, £72. Voted £10

Daughter, aged 63 years, of late L.S.A. who practised in London. No income; receives a home in exchange for services and a small payment. Relieved once, £10 Voted £10.

Daughters, aged 70 years and 66 years, of late L.R.C.P., L.S.A. Edin. who practised in Clackmannan. Have maintained themselves for many years since father's death but now dependent on small pensions amounting to £35 a year. Relieved once, £16. Voted £10.

Widow, aged 45 years, of L.R.C.P., L.R.C.S. Edin. who practised in Sheffield. No income; dependent on a son earning small wages as a labourer. Relieved 11 times, £121. Voted £10.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on July 25th, Mr. HENRY MORRIS, the President, being in the chair.

It was resolved that diplomas of Membership should be issued to 112 successful candidates and that, jointly with the Royal College of Physicians of London, Diplomas in Public Health should be issued to 13 successful candidates.

Mr. L. A. Dunn was elected a member of the Court of Examiners; Mr. A. Pearce Gould was re-elected a member of the Board of Examiners in Dental Surgery; and Mr. W. B. Paterson was re-elected a member of the Dental Section of the Board of Examiners in Dental Surgery.

A letter was read from Mrs. Bennett thanking the Council for its sympathy in connexion with the death of her husband, Professor E. H. Bennett.

It was resolved that the revised edition of Part I. (Man) of the Catalogue of Osteological Specimens in the Museum should be offered for sale at 10s. per copy.

Looking Back.

FROM

THE LANCET, *SATURDAY*, August 1st, 1829.

MEDICAL BENEFIT SOCIETY.

To the Editor of THE LANCET.

SIR,—You have been kind enough to insert my former notes, relative to the formation of a Medical Benefit Society in this metropolis. Permit me to inform your readers, and the profession generally, that among the several communications I have received, *two of the writers have promised very munificent donations* towards the establishment of an institution of the nature I propose. I now beg to state on what plan I should like to see it founded; viz. that of clubs or friendly societies, so that by each member contributing *one or two* guineas per annum, he should be allowed *two* or *three guineas* weekly, when incapacitated from attending to his professional duties; the sum to be fixed by a managing council or committee, elected by the members without favour or affection, whose duty it should also be to confer other privileges when required; as in case of the death of a member or his wife, *or if* his property have been destroyed by fire, or he be in prison for debt, &c. The rules to be prepared by a committee elected for that purpose, confirmed by the members at large, and enrolled according to Act of Parliament. I trust the profession will perceive the necessity of forming an institution for these purposes; and when a member requires assistance, he will have the gratification of obtaining it as his *right*, and not as a matter of *favour*, nor with the chance of experiencing the frowns or reflections of cold-hearted charity, in his applications for relief. These are urgent reasons; I trust the profession will come forward and aid my humble endeavours, and give their assistance to my project, the benefits of which will, hereafter, be duly appreciated. We have seen the great advantages that have attended friendly societies in the humble classes of society, and I can only feel surprised that nothing of the kind should have been attempted before. However, let us verify the proverb, "better late than never," and form a Medical Friendly Society. Any communications and suggestions, therefore, addressed to me, post paid only, twopenny post-office, Brewer Street, shall be attended to. Let me impress on the reader, that however bright our prospects may be at the present moment, sickness and uncontrolled misfortunes may arise, that would render such an institution one of the greatest blessings the profession could experience. Trusting to your kindness in giving this early insertion,

I have the honour to remain,
Your faithful servant,
H. W. DEWHURST, Surg.,
Lecturer on Human and Comparative Anatomy.
July 20, 1829.

P.S.—I have omitted to mention that I would propose to throw open its advantages to all in the profession, whether the apothecary's assistant, or the presidents of the Colleges of Physicians and Surgeons, as well as practitioners, should they choose to embrace them; in fact, it should be open to all, and influenced by none.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8067 births and 3665 deaths were registered during the week ending July 27th. The annual rate of mortality, which had been equal to 12·5, 12·3, and 12·4 per 1000 in the three preceding weeks, declined to 11·9 in the week under notice. During the first four weeks of the current quarter the death-rate in these towns averaged 12·3 per 1000, the rate in London during the same period being 12·0. The lowest rates in the 76 towns last week were 1·2 in Hornsey, 4·9 in Northampton, 5·0 East Ham, and 5·8 in Walthamstow; the highest rates were 17·3 in Walsall, 18·4 in Rochdale, 19·4 in Hanley, and 19·7 in Great Yarmouth. The 3665 deaths in the 76 towns showed a decline of 149 from the number in the previous week, and included 396 which were referred to the principal surgery of tumours of the brain was now established on a scientific basis and its value was being more definitely recognised. It was now possible to operate with very much less risk as regards shock than formerly. There was considerable confusion in the application of the word "operable" to these cases, some authors using it in the sense of curable only. He differentiated three classes of cases which were operable in the sense of curing or relieving the patient: first, those in which the tumour could be completely removed and the patient cured; secondly, those in which partial removal could be effected with marked though temporary benefit; and thirdly, those in which the tumour could not be removed at all but the patient could be afforded relief from the painful symptoms. There was, however, no absolute distinction, since an operation begun as radical might end as palliative, though it was important not to regard palliative operation as a substitute; removal should be carried out wherever possible. There were two kinds of cases in which palliative or decompressive operations were to be recommended, those in which the tumour, though localised, could not be removed, and those in which it could not be localised and yet some relief to the symptoms was necessary. In performing a palliative or decompressive operation the opening should be made over a "silent" or unimportant area and means should be taken to prevent an unnecessarily large hernia cerebri.

Professor W. OSLER (Oxford) held that a great deal of the scepticism in regard to the value of operation in cases of cerebral tumour was the result of the bicipital condition of neurology. He deprecated operation in these cases at the hands of general surgeons and would prefer to see neurology a special department, so that there would not be neurological physicians and surgeons, but medicochirurgical neurologists, properly trained in the anatomical, physiological, clinical, and surgical aspects of their subject. In connexion with the diagnosis of cerebral tumour he drew attention to the curious interval which may occur in the symptoms and illustrated this by reference to a case of his own in which there was a lapse of all the symptoms except the optic neuritis. In syphilitic cases he thought large cerebral gummata would clear up under antisyphilitic treatment without operation. Statistics were badly needed of the results of the two forms of treatment.

Dr. D. B. LEES (London) had observed relief from tapping the ventricles in some cases. The operation was a simple one if Kean's guide were carefully followed. He had also seen it performed with advantage in cases of hydrocephalus at the Children's Hospital, Great Ormond-street. He emphasised the occasional value of prominence of bone over the situation of the tumour in children, especially in cerebellar tumour.

Dr. EDWIN BRAMWELL (Edinburgh) urged that in every case in which operation was undertaken there should be an understanding between the physician and the surgeon as to what should be done, in so far as it is possible to determine that beforehand, including various contingencies such as the subcortical situation of the tumour.

The PRESIDENT of the section mentioned two cases shown by himself in which subtentorial trephining had resulted in permanent relief of symptoms of pressure, in one of them after repeated tapping of the lateral ventricles had failed to do more than give temporary relief.

Dr. RISIEN RUSSELL, in reply, reviewed the remarks of the various speakers and was glad to find that Sir William Macewen agreed in regard to the operative treatment of some syphilitic tumours. He endorsed the remarks of Mr. Gunn and Mr. Armour in regard to the effects of operation and he was very glad that Professor Osler had emphasised the necessity for specialist neurological surgeons.

Dr. A. GARDNER ROBB (Belfast) read a paper entitled

Observations upon the Recent Outbreak of Cerebro-spinal Meningitis in Belfast.

The outbreak began during the last days of December of last year; five members of the same family were suddenly attacked, of whom three recovered and two died. The diagnosis was confirmed by lumbar puncture in the three that recovered and in the two fatal cases by necropsy. On Jan. 24th another family was attacked, five cases occurring, of which four were fatal within 30 hours of the onset. In all there were 230 cases. Four types of the disease were usually described, the acute fulminant, the ordinary, the chronic, and the abortive; to these Dr. Robb added a fifth—the mild, which was important because these cases were liable to be overlooked. He described cases illustrative of each of these types and then dealt with the individual symptoms. Headache was usual, initial vomiting occurred in over 95 per cent., delirium was common, and the temperature varied greatly and was of little value as regards diagnosis or prognosis. In the ordinary type there was a temperature of 102° F. or more on admission to hospital, falling to normal on the second or third day, but in chronic cases there was sometimes a daily variation for seven weeks. The pulse was slow and full in severe cases; a rapid and small pulse was more common and of more favourable import. Rigidity of the neck was constant in all but a few cases; arching of the spine was common in infants, but rare over the age of five years. Squint, always of the internal variety, occurred in 28 per cent. of the cases. Facial paralysis developed in 11, hemiplegia in four, and aphasia in three. Purpuric rashes were observed in less than 20 per cent. Slight general enlargement of lymphatic glands was almost constantly present. Of the 230 cases 162 ended fatally. Three varieties of serum were employed in treatment but appeared to be without influence on the disease. Morphine and opium were employed to relieve symptoms but the greatest relief to the headache was afforded by phenacetin. No relief was obtained from the use of mercury, iodides, bromides, quinine, and the salicylates. The diagnosis was rarely in doubt. Valuable confirmation was obtained by the opsonic index and agglutination methods. After the sixth day they were more reliable than lumbar puncture. They had found no evidence of direct infection by contact.

Professor OSLER pointed out that this disease was most mysterious in its epidemic peculiarities. The disease in its sporadic form was always with us and he held that post-basic meningitis was due to the same organism as the epidemic form.

Dr. F. J. POYNTON (London) said that during the last year there had been a marked increase in the number of cases of post-basic meningitis seen at University College Hospital and Great Ormond-street.

Dr. H. L. MCKISACK (Belfast) said that the evidence of the Belfast attack seemed to indicate that the organism in the post-basic meningitis, if not a different species, was of a different strain from that in the epidemic cases.

Dr. ROBB, in reply, supported Dr. McKisack's remarks and said that opsonic and agglutination experiments with the Belfast cocci showed them to be identical with those from Hamburg, Glasgow, and New York but different from those of post-basic meningitis.

A paper was read by Dr. CLIVE RIVIÈRE (London) on

The Tuberculin Treatment of Tuberculosis in Children.

Cases of tuberculous disease might be divided into two classes—those in which the disease was strictly localised and those in which it was accompanied by some general manifestations. The chief success was obtained in the former class, although much improvement could be produced in the latter. Success or non-success was largely a matter of dosage, most of the bad results being obtained from over dosage. He gave $\frac{1}{10000}$th to $\frac{1}{5000}$th of a milligramme for infants of one year, $\frac{1}{2000}$th for a child of five years, and $\frac{1}{1000}$th after that age. Improvement resulted in three ways: first, an improvement in the general health; secondly, a mental change, the child becoming more cheerful; and thirdly, local healing.

STATE MEDICINE.

WEDNESDAY, JULY 31ST.

The section devoted to State Medicine was held on Wednesday morning, in the rooms of the Young Men's Christian Association, under the presidency of Dr. ARTHUR NEWSHOLME (medical officer of health of Brighton). After a few introductory words of welcome to the members present Dr. Newsholme delivered his presidential address, the subject being

The Coördination of the Public Medical Services.

He said: The greatest successes of medicine have been in the direction of preventing disease rather than of curing it, and even surgery owes a large debt to the bacteriologist and to preventive medicine for its work in germicides. This work of prevention is by no means to be confined to the notifiable infectious diseases, nor even to the non-notifiable class, but beyond these are such diseases as pneumonia, pulmonary tuberculosis, and syphilis, and further still there is the much wider question of preventing diseases from reaching their charge of the 66th Regiment in the Afghan war of 1880 and was present at the affair at Ghirisk, the battle of Maiwand, where he was severely wounded, and throughout the siege of Kandahar (mentioned in despatches and promoted surgeon-major, with the relative rank of lieutenant-colonel, and awarded the medal). He was granted the distinguished service reward in 1901.

Surgeon-Colonel Edmund Greswold McDowell, C.B., A.M.S., on July 26th, at the residence of his son-in-law, at Portland. He entered the service as an assistant surgeon in 1855, became surgeon in 1870, surgeon-major in 1873, brigade surgeon in 1885, and surgeon-colonel in 1886, retiring on half-pay in 1891. He served with the 44th Regiment in the campaign of 1860 in North China, including the action of Sin-ho and the storm and capture of the Taku forts (medal with clasp), and in the Egyptian war of 1882 (medal, Third Class of the Medjidieh, and Khedive's star). He also served in the Sudan expedition under Sir Gerald Graham in 1884 as principal medical officer and was present in the engagements of El Teb and Tamai (twice mentioned in despatches, C.B., and two clasps.)

THE CONVALESCENT HOME AT OSBORNE.

The report for the year ending March, 1907, by the house governor and medical superintendent of the convalescent home intended principally for officers of the Royal navy and army, which was the gift of King Edward VII. to the nation in memory of his mother Queen Victoria, has just been issued as a Parliamentary paper. Lieutenant-Colonel C. R. Kilkelly, C.M.G., in his report states that 330 officers and ladies were admitted during the year. The average duration of each case of illness was 40·3 days. The largest number of admissions (more than half) consisted of officers from the home army. Of the 277 officers admitted 37 belonged to the Royal navy and marines, 11 to the West African and Nigerian Forces, four to West Indian regiments, two to colonial forces, and 58 to the Indian army. The home army supplied 165 cases, most of whom were serving in and invalided from India. Of these cases 15 were from the Royal Army Medical Corps.

INDIAN MEDICAL SERVICE EXAMINATION.

Thirty-four candidates entered for the recent examination for commissions in the Indian Medical Service. Of these 27 qualified, the first 14 being admitted as lieutenants on probation, while one candidate withdrew during the examination. The following is a list of the names of the successful candidates. The total possible number of marks was 5100. 11 of the successful candidates possessed university degrees.

	Marks.		Marks.
H. W. Acton	4120	A. J. H. Russell	3464
V. B. Green-Armytage ...	3834	D. H. Rai	3455
A. N. Dickson	3569	F. S. Smith	3410
A. B. Zorab	3561	A. T. Densham	3403
A. G. Coullie	3549	A. W. Howlett...	3349
R. E. Wright	3540	F. A. Barker	3316
W. H. Biddell	3510	A. N. Thomas	3233

ROYAL ARMY MEDICAL CORPS EXAMINATION.

The following is a list of successful candidates for commissions in the Royal Army Medical Corps at the recent examination in London for which 59 candidates entered. Of the 30 successful candidates 15 possessed university degrees:—

	Marks.		Marks.
T. McC. Phillips	605	C. T. Conyngham	489
H. S. Dickson	591	H. McC. Hanschell	487
G. F. Dawson	586	J. R. Lloyd	485
H. V. B. Byatt	573	H. W. Carson	482
R. E. Todd	561	R. G. S. Gregg	481
T. F. Lumb...	546	H. T. Treves	474
H. Gibson	544	F. T. Dowling	471
C. P. O'Brien Butler	518	J. C. L. Hingston	462
G. Petit	514	F. J. Stuart	457
J. B. Hanafin	512	B. A. Odlum	455
J. A. Renshaw	510	W. R. Spong	448
R. F. O'T. Dickinson	496	J. F. Grant...	447
W. R. O'Farrell...	494	P. H. Hart	441
R. De V. King	493	A. E. B. Jones	440
D. B. McGrigor...	490	A. Hendry	430

His Majesty paid a surprise visit to King Edward VII.'s Hospital for Officers, Grosvenor-gardens, S.W., on July 24th.

AT a meeting of the Totnes (Devon) board of guardians held on July 19th it was decided to erect a new workhouse infirmary.

Correspondence.

"Audi alteram partem."

RICE AND BERI-BERI.

To the Editors of THE LANCET.

SIRS,—In your issue of June 29th, p. 1776, there is an interesting report on rice and beri-beri by Dr. W. Fletcher. Experiments on a small scale have led to varying conclusions. In the experiments in the Kwala Lumpur gaol by Travers and by Hamilton Wright it was shown that of two bodies of men fed from the same stocks of rice, one party might be free from beri-beri when in the other a large number of cases occurred. A close scrutiny of their figures and of the circumstances seemed to me to diminish the value of these experiments, as one party with an average strength of under 40 was too small and the possibility of infection direct or intermediate varied in the two parties. For similar reasons I consider that this experiment of Fletcher's in the lunatic asylum is inconclusive. The parties are not large enough and certain of the figures render it probable that the possibility of infection varied in the two parties.

It must be premised that if beri-beri is an infectious disease, it is not so when neuritis is well marked and that probably the period of infection is short and limited to the earliest stages of the disease, possibly before there are any nerve symptoms, and that even then conditions at present unknown (I suggested pediculi, *not* bed bugs) must also exist. One of the earliest recognised symptoms of beri-beri is an exaggeration of the knee-jerks; by the time this stage is over and the knee-jerks are absent the "poison" has been in action for some time. In Fletcher's table of those fed on Siamese rice 16 had exaggerated knee-jerks and ten of these, or 62 per cent., "developed" beri-beri, as against the general average of 25 per cent. in those in whom knee-jerks were "average" or "impaired," 93 with 22 cases. In my opinion, this points to a considerable number of admissions in the early or prodromal stages of beri-beri to this gang. Of those on the Bengal rice 14 had increased knee-jerks, and none of these developed beri-beri; that is, none of them were in the early stage of beri-beri, and none of the remaining 81 developed the disease.

I exclude from both those, 11 and 23, who had no knee-jerks on admission, as these would be old beri-beri cases in most instances.

There is, therefore, as in so many of these experiments, a possibility, accidental no doubt, of differing liability to infection in the two classes. More detailed information is required as to the occurrence of the disease in the class with increased knee jerks on admission and as regards other points.

The effect of transfer of persons from the one wing to the other is, of course, opposed to the hypothesis of "ground infection" or to infection by bed bugs: this last, I consider, can be excluded from probabilities, as it would not explain the practical immunity of the Tamils from the disease. It does not exclude the possibility of transfer of the disease by parasites that usually remain attached to their hosts, such as pediculi. I think it is to be regretted that Braddon's terms "cured" and "uncured" should be used instead of say "Indian" and "Rangoon," as they tend to cause a prejudice. The rice used in England is the "uncured" rice.

I am, Sirs, yours faithfully,

July 22nd. C. W. DANIELS.

CHILDREN'S COUNTRY HOLIDAYS FUND.

To the Editors of THE LANCET.

SIRS,—Now the holiday season is with us once more, and all those who are able to are leaving London, may I venture to remind your readers of the vast child population which, if unassisted by the public, will spend the month of August in the heat of London? The public elementary schools are now closed and a great majority of the 800,000 children that attend them will spend their month's holiday in stuffy and over-crowded rooms. Many of them are delicate and are little fitted to withstand the strain which is inflicted upon them by the heat and incessant noise. It is the aim of the Children's Country Holidays Fund to send as many of these objection to it. There was undoubtedly a need for coördination between the hospital and the workhouse infirmary so that the empty beds in hospitals could be utilised. He compared the French system and pointed out that in France the money was raised in such a manner that the tax was not felt.

Dr. J. Sinclair Holden (Sudbury) spoke as a rural medical officer of health on the importance of reaching the home through parish and district nurses. Such nurses, though not municipalised, are often assisted by grants.

Mr. Herbert Jones (Hereford) spoke as a representative of the overworked body of representatives on the number of ethical disputes. If the public medical service were once organised such ethical matters would readily be solved. Hospital abuse was even more demoralising than pauperism to those who committed it.

Professor H. R. Kenwood (London) felt wholly in accord with the principles enunciated in the address, but he also regretted greatly that no opportunity was given for a detailed discussion of the public medical service.

Dr. J E. Molson (Worthing) felt that some Government provision should be made by coördinating the present system of school inspection and Poor-law with the present sanitary departments.

Dr. J. H. H. Manley (West Bromwich) pointed out that the scheme formulated by the President was absolutely part of Socialist views which would eventually prevail. The combination of the Poor-law administration with the local sanitary administration was already in sight; the municipalisation of voluntary hospitals, long ago advocated by Havelock Ellis, must follow; and then when Socialist views prevailed the working man would no longer condescend to accept charity, not even free boots and free breakfasts. Opposition to the proposal was certain but its evolution was also certain. It was as certain to come as free education had been and he should rejoice to see it.

Dr. E J. Slade-King (Ilfracombe) said that there was a spirit of democracy abroad and it was for the medical profession to consider the questions which were arising. He alluded to the Poor-law Commission now sitting and to the difficulty of rural nursing. The ignorance of rural mothers as to their children was colossal. They fed their children too little, too often, and on the wrong food. The storage of food was even worse and the milk was polluted as soon as it arrived and put in contact with the pig's food.

Dr. A. H. Bygott (Birmingham) also emphasised the grave results arising from delay.

Mr. Sack Noy Scott (Plymstock) failed to see how the ordinary private practitioner could be compelled to come in the scheme. The process of compulsion seemed to him to present many difficulties but at the same time he felt himself compelled to assent to the principles enunciated by Dr. Newsholme.

Dr. Walter Brown (medical officer of health of Ayr) said that he thought they were going in the direction of State socialism but they must not forget the general practitioner and see that he was paid for what he did. The tendency of the laity was to expect the general practitioner to do something for nothing.

The President of the section briefly replied, pointing out that his paper purposely avoided detail; the details would be found in his evidence before the Poor-law Commission. This was really a "second reading" and for the purpose of enunciating a principle which he was quite sure would eventually commend itself.

Two papers were then read relating to

Vaccination in its Preventive and Administrative Aspects.

Mr. Garrett Horder dealt with the hardships which would be endured by reducing the fee and the number of visits which were being required by the Government coupled with the clerical work entailed upon public vaccinators.

Dr. A. W. Gilchrist (Nice) in a paper entitled

The Necessity of Increasing the Degree of Immunity against Small-pox,

said: 1. The further relaxation of the law of compulsory vaccination in England entails the necessity upon the intelligent sections of the community of increasing individual immunity against small-pox by repeated vaccinations. 2. Epidemic and infectious diseases can be shown to obey general sociological laws in their evolution and incidence; the crusades caused the wide-spread prevalence of leprosy and plague, the circumstances attending the discovery of America induced the appearance or the diffusion of syphilis, and the Mahomedan invasion of Asia brought as its sequel the epidemic form of small-pox. The recent recrudescence of this last disease in the West is thus attributable to several causes: (1) The three late wars, Spanish-American, South African, and Russo Japanese; (2) the failure or defective activity of our vaccines; (3) the increasing virulence of the more rapidly imported disease; and (4) the growing number of the unprotected. 3. Most civilised countries, in contrast to England, are assuming a more decided attitude of defence against the disease. Thus, France has promulgated a new sanitary (public health) law more complete even than the German enactments. It might be added that this law partakes to a certain extent of a military character, the French remembering that in the Franco-German war of 1870 their losses from small-pox were equivalent to the strength of a *corps d'armée* while those of the German's were insignificant. 4. The actual conditions demand a more thorough knowledge of small-pox on the part of medical men. The disease undergoes modifications of type and "*epidemies frustes*" often conferring unsuspected immunity have been described. Here, again, England compares unfavourably with some foreign states. In a recent trial an English medical man pleading ignorance of a case of hæmorrhagic small-pox was acquitted.

A short discussion followed in which Professor Kenwood (who had now taken the chair), Dr. F. J. H. Coutts (Blackpool), and Mr. Sack Noy Scott took part, and a motion was carried calling upon the Council of the Association to approach the Local Government Board on the subject of the new vaccination order.

LARYNGOLOGY AND OTOLOGY.

Wednesday, July, 31st.

This section opened with a discussion on

The Differential Diagnosis of Tuberculous, Syphilitic, and Malignant Disease of the Larynx,

by Sir Felix Semon, K.C.V.O. (London), and Dr. W. Jobson Horne (London).

The following members subsequently joined in the discussion: Dr. N. C. Haring (Manchester), Mr. Herbert Tilley (London), Dr. J. Dundas Grant (London), Dr. G. W. Hill (London), Dr. Scanes Spicer (London), Dr. H. S. Birkett (Montreal), Dr. W. S. Syme (Glasgow), Dr. Adolph Bronner (Bradford), Dr. J. B. Ball (London), Dr. P. Watson Williams (Bristol). The President (Dr. R. McKenzie Johnston of Edinburgh) summed up the discussion and Sir Felix Semon and Dr. Horne replied.

A paper was read by Mr. W. Stuart-Low (London) on

Submucous Turbinectomy.

The paper was discussed by Dr. Hill, Dr. Jobson Horne, and Dr. Watson Williams, and Mr. Stuart-Low replied.

In the absence of the author one of the secretaries read a paper by Dr. Robert Fullerton (Glasgow) on

A Tumour which was removed from the Right Tonsil and which is regarded as being a Teratoma.

The paper was illustrated with drawings and microscopic slides of the tumour.

OPHTHALMOLOGY.

Wednesday, July 31st.

The President, Dr. L. H. Tosswill (Exeter), made some opening remarks, in which he pointed out that the West of England Eye Infirmary at Exeter was founded only four years after Moorfields.

Dr. E Landolt (Paris) opened the discussion on the Construction and Manipulation of the Principal Instruments used in Eye Surgery. Some discussion took place, all the speakers agreeing with Dr. Landolt.

Mr. Simeon Snell (Sheffield) read a paper on An Inquiry into the Cause of Blindness in 350 Inmates of a Blind School. Very nearly half of the cases of blindness were due to ophthalmia neonatorum, which, he pointed out, was an absolutely preventable disease; the other chief causes were optic atrophy, congenital cataract, and sympathetic ophthalmitis.

Mr. Sydney Stephenson (London) moved the following motion:—

> That in the opinion of this section the British Medical Association should take steps to the prevention of ophthalmia neonatorum.

that this is impossible, as no relation exists between the resistance of the body and the tension of the current on the spinthermeter. For example, if in place of the body a spinthermeter was substituted it would be found that the distance between each of the points of the spinthermeters would be equal to one-half the distance measured between the points of the first one. Again, if the body was placed in circuit with the spinthermeter and the resistance of the former gradually *reduced to a short circuit, it would be found that the voltage* on the spinthermeter would be reduced to *nil*. The voltage is annulled in consequence of a short circuit having been made, showing that resistance bears no relation to the potential difference. Consequently, whatever the resistance of the body may be, when placed in circuit, the same voltage would be measured between the apparatus and earth as that on the body. The body when thus placed in circuit would take the difference in current which could be registered on a meter if it were connected in series, the voltage remaining constant. If the current measured on this meter was added to the current measured on a second meter, the latter being connected to zero, it would be found that the total of the two readings on the meters would be equal to the current passing to zero when the body was short-circuited.

The above would be in ratio to any resistance placed in the external circuit, showing that resistance does not cause a drop in potential or annul voltage. The contention that 25 feet of No. 14 copper wire causes a large drop of potential is, I venture to assert, not tenable, as the resistance of this length of wire equals approximately 0·15 ohms. The copper wire short circuits the apparatus, and the apparent drop in potential on the spinthermeter is due to this short-circuiting. The physical data given by Dr. Sloan under which his experiments were carried out are such as to question the conclusions arrived at by him as to the physiological effects of high-frequency high potential currents upon the body. In order to study the physiological effects resulting from the action of high-frequency currents on the body it is essential that a given wattage acting over a given time be maintained on it, the wattage being obtained from ampèrage and not from voltage. Further, it is necessary that the electrodes be kept at the normal temperature of the body, otherwise no accurate records can be made, and this is particularly the case when observations are being taken regarding the increase of temperature due to these currents.

As to the query what effects would be observed if the same *amount of current was maintained* but at different voltages, the answer to this is, as the voltage is increased a corresponding fall in current will take place, and contrariwise until a minimum voltage of from 80 to 100 is obtained. At this voltage the maximum current which can be tolerated by the body without injuring it is five ampères, or 400 watts. My contention is that it is the quantity of current which passes through the body that produces the physiological changes in it, but the wattage must be obtained by current and not voltage. Should my statement be challenged the matter can be easily set at rest by a comparative study of the effects of these currents upon the body under the following conditions. Let the body be subjected to 300 watts, the wattage being made up as follows: first, 60,000 volts at five milliampères; and secondly, 100 volts at three ampères.

In conclusion, I may say that those who hold that when the body is subjected to these high voltages only a very small quantity of current is passed through it are fully justified in their contention. I agree with Dr. Sloan that it would be well if a scientific investigation committee was appointed to consider the whole matter relating to the administration of these high potential currents in order that the subject may be placed upon a sound scientific basis.

I am, Sirs, yours faithfully,

Cardiff, July 28th, 1907. J. CUNNINGHAM BOWIE.

TRYPSIN IN THE TREATMENT OF CANCER.

To the Editors of THE LANCET.

SIRS,—I have read with the greatest interest the able and impartial leading article on the above subject in THE LANCET of July 27th in which the independent theories of pancreatic treatment by Dr. J. Beard and by Dr. J. A. Shaw-Mackenzie are clearly differentiated. In view, however, of your statement that "so far theory only has spoken but Dr. Beard proceeded to test his theory by the injection of trypsin into some mice which had been inoculated with Jensen's mouse tumour," whatever the value of the treatment may be, I desire to draw your attention to the fact that on the publication of Dr. Beard's communication in THE LANCET of Feb. 4th, 1905, p. 281, suggesting pancreatic treatment, Dr. Shaw-Mackenzie had already proceeded to put his own theory into practice by injections of trypsin, originally prepared for him by Mr. F. W. Gamble, and by pancreatic preparations, orally and locally, as noted and first published in THE LANCET of Feb. 11th, 1905, p. 386. I am, moreover, in a position to speak with authority in this matter, inasmuch as Dr. Shaw-Mackenzie was associated with me in the treatment of some cases of inoperable cancer under my care in the Royal Hospital, Chelsea, and when his researches were being made. To my knowledge more than one patient had apparently derived advantage from the trypsin treatment before any experiments on mice were made, nearly a year later.

I am, Sirs, yours faithfully,

THOS. LIGERTWOOD, C.B., M.D. Aberd.

Chelsea, S.W., July 27th, 1907.

THE MEDICAL USES OF ESPERANTO.

To the Editors of THE LANCET.

SIRS,—An International Congress of Esperantists is to be held at Cambridge in the month of August. Necessary preparations are bringing the great auxiliary language into the ken of many English folk who have hitherto been blind to its existence, and it is certain that in two months' time very few newspaper readers will retain their vague impression that Esperanto is a sort of grass. Even already, it may be, most British medical men will be interested to learn how Esperanto can be of use to them in their profession.

Its uses.—Medical work, more than most kinds of work, embodies the principle of universal brotherhood. The human frame has been much the same in all historic ages; health, all the world over, is to be had by obeying the same few laws; disease, in all known races, arises from similar causes and is amenable to similar treatment. And the grand impulse which prompts our service in the cure of disease and the preservation of health is happily common to all peoples. Surely, then, the medical worker, of all workers, needs an international tongue which can effect an understanding between him and all who need his help, as well as between him and all those who can assist him to greater helpfulness. That there is use for such a language in the relationship between patient and medic (and why not medic? *cf.*, cleric, mechanic, stoic, &c.) even the most stay-at-home practitioner must feel. Travel is easy nowadays, and people are so enterprising that it is common enough for foreigners to come to this country with little or no knowledge of English. In my own small experience I have had to deal with French, German, Italian, and Japanese patients who could not speak my mother tongue. The medic who travels abroad is, of course, much more liable to be thus handicapped. In such a predicament Esperanto becomes increasingly available. Already there are 35,000 Esperantists who have taken the trouble to register their names. And others without number, in over 100 different countries, have acquired the *lingvo*. That there is use for such a language in international medical congresses is even more obvious. Few English medics can understand a French, or German, or Italian speaker; and still fewer can discourse in these tongues. When it comes to Norwegian, Russian, or Dutch the case is worse. Thus our polyglot medical gatherings, which ought to be so helpful, must surely be an exasperating linguistic Babel. That there is use for such a language in international medical literature is more evident still. At present valuable work is being recorded in all manner of languages. Much of it is translated and re-translated into a variety of different tongues, but at what an expense of time and labour and printed space! Surely it would be an economy for all if every writing that promotes the health of man were accessible in one easy language. One translation would then serve for the whole world—nay, before long no translation would be required; the worker would himself record his results in the international language.

These considerations are so evident that for centuries men have been trying to select or invent an international tongue. Three plans have been possible: 1. Selection of a dead language, such as Greek or Latin. This plan has had a fair trial for centuries and it has failed. These languages are to consider the merits of various beverages, and again at the next stall some of the latest developments of x ray apparatus were to be seen. The largest representation was perhaps that of surgical appliances and hospital aseptic furniture; next, possibly, came drugs, these forming in general a very elegant display. Certain of the exhibits were of a strictly scientific character and more particularly those in which the x ray apparatus and fine synthetics were chiefly in evidence. We do not remember any previous exhibition being arranged with a greater regard to the visitor's comfort. A writing-room was provided, there was a refreshment lounge, and in an annexe some additional exhibits were shown.

Pursuing the course adopted on previous occasions, we deal with the sections in the following order: (1) Surgical Instruments and Appliances; (2) Drugs; (3) Foods and Food Products; (4) Sanitary Appliances; (5) Mineral Waters, Beverages, &c.; (6) Publications; and (7) Miscellaneous Exhibits.

I.—SURGICAL APPLIANCES.

Surgical appliances and the accessories of the operating theatre, sterilising apparatus, operating tables, sinks, &c., formed a very pronounced feature of the exhibition this year. What everyone must have admitted to be a very fine exhibit coming in this category was that of Messrs. Arnold and Sons, of West Smithfield, London, E.C.; their stall, occupying the whole of the stage, formed a very complete display of up-to-date instruments and hospital appliances. The exhibit included the improved high-pressure steam sterilisers in both horizontal and vertical form, the design of which was suggested by Mr. W. Bruce Clarke. A working model was exhibited. Provision is made in this apparatus for absolute sterilisation and accidental contamination is carefully guarded against. The instruments included Kollmann's anterior and posterior urethral dilators, Heath's mastoid instruments, and a selection of gynæcological instruments. There was a large selection also of aseptic hospital furniture. Messrs. Harry W. Cox, Limited, of Rosebery-avenue, London, E.C., exhibited quite a large selection of apparatus connected with x ray work and high-frequency applications. Here were hospital outfits for use in the ward, including a coil giving a greatly intensified spark, a new mercury interrupter, and an apparatus for the light treatment of ringworm. Messrs Mayer and Meltzer, of 71, Great Portland-street, London, W., presented to view a number of improved designs of surgical instruments which attracted the interest of the surgical visitors. There were also instruments of approved design used in laryngological, rhinological, and otological practice. They exhibited also a combined midwifery douche and steriliser. In the horizontal position this can be used as a steriliser, while in the vertical position it answers the purpose of a douche. Amongst the electro-medical apparatus shown by the Sanitas Electrical Company of 61, New-Cavendish-street, London, W., was the "Multostat" which is described as a new universal apparatus just produced and exhibited for the first time. It consumes very little current and can be attached to any continuous supply. It may be applied to all electro-therapeutic purposes. The exhibit included a very ingeniously devised x-ray couch and a bath known as the Schnée 4 cell bath for administering the current through the body either completely or locally. Close by was the exhibit of the Medical Supply Association, of 228 and 230, Gray's Inn-road, London, W.C., comprising hospital furniture, surgical instruments, dressings, anæsthetics, and electrical apparatus. They exhibited an anæsthetic mixture for administration locally which avoids the danger of sepsis since it contains an antiseptic, while it is stated to be free from ordinary poisoning effects, as the solution is only one-twentieth strength of the B.P. cocaine solution for hypodermic injection. Amongst the electrical apparatus exhibited was the latest type of interrupter known as the Gaiffe auto-motor mercury jet interrupter which dispenses with an independent driving motor as well as brushes and bands.

Messrs. Allen and Hanburys, Limited, of 48, Wigmore-street, Cavendish-square, London, W., presented to view a very interesting and wide assortment of surgical appliances and aseptic hospital accessories. Their exhibits were so numerous as to occupy three stalls. The exhibits included Japanese ice-bags, an aseptic hypodermic syringe for the watch-chain, syringes for the administration of novocaine, aseptic operating theatre furniture in phosphor bronze, German silver, and white enamel steel, high-pressure sterilisers, and portable dressing sterilisers which can be used over the kitchen fire or on an oil lamp or gas burner. It represents a cheap and an efficient steriliser for dressings.

The Holborn Surgical Instrument Company, Limited, of 26, Thavies Inn, Holborn-circus, London, E.C., exhibited on one stall an assortment of aseptic furniture, chief amongst which was the Holborn high-pressure steam steriliser which works at 250° F.; the steam penetrates everything and the process of sterilisation is complete, the dressings being dry after the treatment. This company's other stall was devoted to the display of surgical instruments; the selection was wide and calculated to meet all the requirements of surgery. Mention may be made in particular of a convenient set made for medical men commencing a general practice. High-class workmanship was the feature of the admirable display of surgical instruments and aseptic hospital furniture by Messrs. Down Brothers, Limited, of 21, St. Thomas-street, London, S.E. The exhibit included the "St. George's" operating table, the "St. Thomas's" swing pattern operation table, sterilisers, and a number of forceps, catheters, &c., designed by various surgeons.

The exhibit of Messrs. Watson and Sons, of 313, High Holborn, London, W.C., of electro-therapeutic apparatus attracted considerable attention by reason chiefly of the wonderful detail shown in the skiagraphs produced by the "intensified" induction coil. With this apparatus skiagraphs can be taken of any part of the human body with exposures varying from one to five seconds. The "intensified" induction coil works in conjunction with a new form of mercury interrupter which is worked with a gas dielectric instead of the usual liquid and accordingly runs for a relatively unlimited period without the mercury requiring to be cleaned. Moreover, the amount of mercury required is not more than one pound in weight.

The Repello clinical thermometer, which does not require shaking down to reset, has already been described in our columns. Mr. G. H. Zeal, of 82, Turnmill-street, London, E.C., exhibited many patterns of this instrument. The latest design is the aseptic thermometer which fits into a container like a stoppered bottle in which cotton-wool may be kept saturated with carbolic acid. Messrs. S. Maw, Son and Sons, of 7 to 12, Aldersgate-street, London, E.C., occupied one stall for the exhibition of surgical instruments and another for aseptic furniture. Amongst the former were many instruments designed by well-known surgeons, and there were also shown sterilised catheters and dressings. The aseptic furniture included a new operation table which can be raised or lowered by simply turning a wheel at the head of the table. Other designs of operating tables were shown and also a high-pressure steriliser. Cotton lints, absorbent gauze tissues, bandages of various kinds, and compressed dressings were the feature of the exhibit of the Liverpool Lint Company of Mark-street Mills, Netherfield-road, North Liverpool. A fine selection of instruments and appliances of modern design was shown by Messrs. John Weiss and Son, Limited, of 287, Oxford-street, London, W. The exhibit included various patterns of ophthalmic instruments. Mr. Thomas Hawksley, of 357, Oxford-street, London, W., exhibited an apparatus which graphically recorded blood pressure and is known as Dr. Erlanger's sphygmomanometer, together with other apparatus designed for the same purpose. The clinical polygraph, designed by Dr. A. G. Gibson, was also exhibited, the apparatus being suitable for clinical use for recording the movements of various organs of the body.

The Equipoise Couch Company of Ashford, Kent, demonstrated the advantages of their specialities, the Equipoise mattress, lounge, bath chair, and chair on the orchestra platform. This system of construction enables the user to sit, lie, or recline in any comfortable position, the position being very easily adjusted and without any special effort. The merits of these appliances are well summed up in the phrase of the inventors, "any position by volition." Messrs. George Gale and Son of the Union Works, Birmingham, exhibited a number of bedsteads designed for invalids and others and known under the title of Lawson Tait spring bedsteads. It is interesting to note that these beds are designed in such a way as to encourage the keeping of all parts clean, while the absence of sharp corners, &c., minimises the risks of injury to patients. Messrs. Philip Harris and Co., Limited, of 144 and 146, Edmund-street, Birmingham, exhibited three appliances under the generic title "perfectum." The first was the perfectum surgery drug cabinet, the second a surgery couch, and the third a bacteriological cabinet. The exhibit was decorated with certain medicinal plants which can be cultivated in Great

A MODEST PROPOSAL FOR SOLVING THE ECONOMIC DIFFICULTIES OF THIS KINGDOM AND PREVENTING IT BECOMING OVER-POPULATED WITH NECESSITOUS AND MISCHIEVOUS PEOPLE.

To the Editors of THE LANCET.

SIRS,—It is a melancholy object to those who walk through this town of London or travel in the country when they see the streets, the roads, and the wayside commons crowded with tramping persons of both sexes, followed by two or three small children, all in rags and unable to obtain work which they probably could not perform if they could find it. I think it is agreed by all parties that this prodigious number of children in the arms, or on the backs, or at the heels of their mothers is in the present condition of the kingdom a very great additional grievance, and, therefore, whoever could find a fair, cheap, and easy method of passing these children out of existence would deserve so well of the public as to have his statue set up as the preserver of the economic status of the nation. But my intention is very far from being confined to provide only for professed beggars and their children. The project which I am about to recommend will not only provide for the natural (and therefore humane) extinction of that class, but also for the extinction of a class of persons who affect a violent sedition against any and all rules and regulations which may have been laid down for their control by the *Government* of the State.

If any person could suggest a method by which all the children of the poorest classes who are unable to support themselves or their families should be destroyed when under five years old, and that one quarter at least of the adult portion of that class should in each year perish, and this by a distemper rapid and comparatively painless when once acquired, it would be the obvious duty of the controllers of this kingdom to allow them to acquire this distemper if it can reasonably be shown that they do prefer to do so, which we are told none can doubt. That there was 200 years ago such a distemper is well known to those who have read the books written at that period or who have studied the parish registers or the "bills of mortality" which have recorded the deaths. It is well known to those students of past records that this distemper would at intervals take off annually half the population of any one village or township and destroy without fail every child under five years of age.

To provide for a return of this ancient and salutary state of things it is only necessary to repeal an Act of Parliament which is expensive in its administration, abhorrent to the bulk of the population, and is only useful and desirable because it affords a means of securing votes at Parliamentary and municipal elections for a certain section of professional politicians. It is not even necessary to repeal the Acts of Parliament, for it is within the power of one of the Ministers of State to sweep away this wicked interference with natural laws by "a stroke of the pen," as this Minister has himself declared. But as to myself having been wearied out for many years combining with others to offer the Government of this country good advice as to protecting the people from this distemper, and at length utterly despairing of success, I have fortunately fallen upon this proposal, which, as it is wholly new, so it has something solid and real, of no expense and little trouble, full in our own power, and since the essence of good government is to seek the favour of the most ignorant and least educated we can incur no danger in disobliging England.

I profess in the sincerity of my heart that I have not the least personal interest in endeavouring to promote this necessary work, having no other motive than the public good of my country by providing for infants and relieving the poor. For myself, I shall be a loser of nearly £20 sterling per annum, having for many years exercised the infamous profession which has succeeded in preventing the occurrence of this distemper and having been paid the same wages for my work as are earned by a common carpenter. I have no children whom I am likely to lose and mourn, as the youngest is 15 years old, and while all of them have been vaccinated every five years my wife is past child-bearing.

I am, Sirs, yours faithfully,

July 29th, 1907. J——N S——FT.

CERTIFYING SURGEONS AND THE WORKMEN'S COMPENSATION ACT, 1906.

To the Editors of THE LANCET.

SIRS,—The important duties of certifying factory surgeons have been underpaid ever since the institution of the appointment, and the small fees to which your correspondent draws attention are only what one would expect from past experience. For instance, the fee which the Government in its wisdom regards as proper remuneration for the examination of a young person employed in a factory, with special reference to the work which such young person will have to do and the hygienic condition of the shop in which he has to work, is the sum of 6*d*., which, moreover, includes the keeping of a record of the examination for the purposes of an annual report, for which no fee is considered necessary.

As an example of "sweating" this would probably be unique were it not put completely in the shade by the fees allowed for reporting on cases of industrial poison, such as lead. On notice of such a case being received by the certifying surgeon the factory where the case occurs must be visited with a view to finding out the reason of lead being absorbed by the workman, the special exhaust ventilation must be overhauled to see whether it is in working order and in constant use, and the facilities provided for washing must be inspected. This being done the patient must be visited and thoroughly examined. The degree of anæmia must be ascertained, presumably by means of a blood count, and the exact amount of paralysis, if present, determined by means of electrical reactions. Having thus ascertained the facts of the case a detailed report covering one and half sides of closely written foolscap must be made out and forwarded without delay. For this work the fee of, not two guineas as one might reasonably expect, but 3*s*., is forwarded in the early part of the following year, provided that an account on the given form is duly sent up within the first week of the year.

The new Compensation Act increases enormously the responsibility of this work, as it is always liable to be reviewed by the medical referee, who, by the way, is not empowered to obtain a consultation with the certifying surgeon, and a careless or hasty examination might lead to faulty diagnosis, implying injustice either to the workman or his employer. The sum of 5*s*. paid under the Compensation Act is a small advance on this, but how is the certifying surgeon to afford the time necessary to do justice to himself in a case of ankylostomiasis, where it is essential to examine microscopically either the blood or the fæces, or in a doubtful case of anthrax when a bacteriological examination is necessary? The amount of careful work which certifying surgeons have to do is so great and is increasing so much year by year that it is almost impossible for a man earning his own living to do it conscientiously and in my opinion the time has come for the profession generally to come to the aid of the certifying surgeon in order to help him to get a remuneration in accordance with the time and trouble taken in his work.

I am, Sirs, yours faithfully,

July 27th, 1907. C. F. S.

WEST HAM HOSPITAL.—On July 27th the Duchess of Marlborough laid the foundation-stone of the new West Ham Hospital extension at Stratford. Replying to a vote of thanks to the extension committee, Dr. P. J. S. Nicoll, honorary secretary of that committee, referred to the help which the Duchess of Marlborough had rendered to the fund and on behalf of the committee presented to her Grace an illuminated address which expressed "sincere and heartfelt thanks to her Grace for her many acts of thoughtful kindness and invaluable assistance rendered." After the ceremony an "At Home" was held and an inspection of the buildings was made by the company. The new buildings will contain a casualty department, an operating theatre, two additional wards containing 20 beds each, and extra accommodation for the nursing staff. The estimated cost of the extension is about £20,000, and towards this amount nearly £14,000 have already been subscribed.

on the one hand and of valerian on the other. The exhibit also included styptol, a uterine hæmostatic; santyl, the salicylic ester of santal oil; styracol containing guaiacol but without the disagreeable taste of that substance; and, lastly, diuretin, which is said to be useful in dropsy and cardiac asthma and in the treatment of arterio-sclerosis. A very effective exhibit was that of Messrs. Wyley's, Limited, of Coventry. The exhibit throughout gave evidence of pharmaceutical skill and included preparations of heroin compounds, medicinal syrups, and standardised tinctures. The exhibit included a well-designed dispensing cabinet fitted complete for a branch surgery.

(To be concluded.)

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the respective meetings of the above Colleges on July 25th diplomas of L.R.C.P. and M.R.C.S. were conferred upon the under-mentioned gentlemen who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Examining Board in England:—

Samuel Henry Cummings Air, Guy's Hospital; Norman George
Allin, M.B., C.M. Toronto, Toronto University and Middlesex
Hospital; Manekjee Dhanjishaw Anklesaria, L.M. & S. Bombay,
Bombay University and Middlesex Hospital; Raymond Ebenezer
Apperly, Middlesex Hospital; James Appleyard, University
College Hospital; Frederick William Aris, M.D. McGill Uni-
versity, Montreal and London Hospital; Harold Percivall Aubrey,
L.D.S. Eng., Guy's Hospital; Frederick James Fitzmaurice
Barrington, University College Hospital; Richard Lavington
Barwick, Cambridge University and St. Thomas's Hospital; John
Willoughby Butler Bean, B.A. Cantab., Cambridge University and
St. Bartholomew's Hospital; Thomas Herbert Cecil Benians,
London Hospital; Horace Simeon Berry, M.A. Cantab., Cambridge
University and St. Bartholomew's Hospital; Francis Arnot
Blackader Bett, M.B., Ch.B., New Zealand University*; Raymond
Glendore Bingham, St. Thomas's Hospital; John William Bint-
cliffe, Manchester University and London Hospital; Frederick
Richard Bray, Charing Cross Hospital; Angel Camacho, Charing
Cross Hospital; Leonard Buckell Cane, B.A. Cantab., Cambridge
University and St. Bartholomew's Hospital; Hildred Bertram
Carlyll, Cambridge University and Guy's Hospital; Robert Godwin
Chase, B.A. Cantab., Cambridge University and Guy's Hospital;

* Diploma of M.R.C.S. previously conferred on June 13th, 1907.

Diplomas in Public Health were granted by the Royal College of Surgeons of England in conjunction with the Royal College of Physicians of London to the under-mentioned gentlemen:—

Isidore McWilliam Bourke, M.R.C.S., L.R.C.P., Middlesex and St.
George's Hospitals; Edwin Eckersley, Lieutenant-Colonel
R.A.M.C., M.B., C.M. Edin., Edinburgh University; Robert John
Ewart, F.R.C.S., L.R.C.P. Lond., M.D. Vict., Liverpool and
Manchester Universities; Matthew Henry Gregson Foll, Captain
R.A.M.C., M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Harry
Andrew Foy, L.M. & S. Bombay, L.R.C.P. & S. Edin., L.F.P. & S.
Glasg., University College Hospital; Frederic William Lewis,
M.B. Lond., St. Mary's Hospital; William Glen Liston, Captain
I.M.S., M.D., Ch.B. Glasg., Glasgow University; Edward Daniell
Parsons, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital;
Wentworth Francis Tyndale C.M.G., Captain R.A.M.C., M.R.C.S.,
L.R.C.P., M.B. Lond., St. George's Hospital; Brian Watts, Captain
R.A.M.C., M.R.C.S., L.R.C.P., M.D. Brux., Sheffield University
and London Hospital; Bernard Harry Wedd, M.R.C.S., L.R.C.P.,
M.D. Lond., Guy's and King's College Hospitals; James Edwin
Wilson, M.B., B.Ch., R.U.I., Belfast and Birmingham Universities;
and Charles Rawdon Wood, M.R.C.S., L.R.C.P., M.D., B.S.
Durham, University College Hospital and Durham University.

UNIVERSITY OF LONDON.—At the intermediate examination in medicine held recently the following candidates satisfied the examiners:—

Alister Ralph S. Alexander, University College; Richard William
Annison, Middlesex Hospital; William Reginald Ward Asplen,
Westminster Hospital and King's College; Ethel Marian Baker,
University of Liverpool; Richard Pitt Ballard, Guy's Hospital;
Alfred David Eldred Bayliss and Joseph Dudley Benjafield, Uni-
versity College; Barbara Broster, London (Royal Free Hospital)
School of Medicine for Women; Hugh Leonard Burton, King's
College; Ronald Herbert Candy, London Hospital; Henry William
Catto, Guy's Hospital; †Nina Gertrude Cotton, London (Royal Free
Hospital) School of Medicine for Women; †‡Arthur Neville Cox,
Guy's Hospital; Hazel Haward Cuthbert, London (Royal Free
Hospital) School of Medicine for Women; William Chalmers Dale,
St. Bartholomew's Hospital; William Allen Daley, B.Sc., Univer-
sity of Liverpool; Vaman Ganesh Desai, King's College; Geoffrey
Dunderdale, John Beatson Dunning, and Emile Marc Antoine
Duvivier, Guy's Hospital; Gerard Ferdinand E. Dyke, University
College, Cardiff; ‡§Florence Mary Edmonds, London (Royal Free
Hospital) School of Medicine for Women; Roger Bellis Edwards,
University of Liverpool; James Philip Elias, Victoria University
of Manchester; Arthur Oxley English, Middlesex Hospital; Harold
Gardiner, Guy's Hospital; †¶Douglas Green, University of
Sheffield; Thomas Hare, St. Mary's Hospital; Wilfrid Lawrence
Hibbert and Guy Reginald Hind, Guy's Hospital; ‡Joseph
Stanley Hopwood, St Thomas's Hospital; †Stanley Hoyte, King's
College; Maurice Lionel Corrie Irvine, St. Thomas's Hospital;
*¶Geoffrey Jefferson, Victoria University of Manchester; Evan
Hugh Jones, St. Thomas's Hospital; Henry Goff Kilner,
Middlesex Hospital; Ernest Charles Lindsay, London Hospital;
†Arthur Gordon Haynes Lovell, St. Mary's Hospital; George
Gibson Lyttle, Queen's College Belfast; Emily Clara Macirone,
London (Royal Free Hospital) School of Medicine for Women;
George Maxted, Guy's Hospital; *¶Bernard Constable Maybury,
St. Thomas's Hospital; John Harry Me rs, St. Mary's Hospital;
Douglas Ashley Mitchell, Guy's Hospital; Stella Myers, London
(Royal Free Hospital) School of Medicine for Women; Arthur
Griffith William Owen, University of Liverpool; Mary Minnie
Patterson London (Royal Free Hospital) School of Medicine for
Women; Wilfrid Langrish Pink, St. Thomas's Hospital; †‡Harry
Platt, Victoria University of Manchester; Norbert Leo Maxwell
Reader, University of Leeds; ‡Ernest Edward Andrew T. Rigg,
University College; †Arthur Leyland Robinson, University of

As matters now stand there is no law nor even any well-established custom. It is all optional. The guardians may or may not grant a pension. The worst of it is that the dispensary medical officer does not know beforehand what will happen. He must resign first, then if he is sufficiently popular and adroitly supported the guardians may perhaps vote him a pension. The unfortunate practitioner is not only in doubt whether he will get a pension but he is still more in the dark as to what the amount may be.

Many attempts have been made to obtain a legal settlement of this question and a law was actually enacted, but in consequence of a ridiculous error in its phraseology it has only been of benefit to some ten or 12 persons. The law said that to receive a pension the dispensary medical officer must be more than 60 years old and have been 20 years in service on the day the Act came into force—namely, Nov. 1st, 1898. The framers of the Act forgot to say what was to happen after Nov. 1st, 1898 Therefore, having securing pensions for the 10 or 12 medical men who happened to fulfil the stipulated conditions on that one and special day the law was taken as not applying to anyone else. There never was a better case of the letter killing the spirit, the purpose of an enactment Then, again, the men who have now reached, or are nearing, the age when they ought to receive a pension were appointed to their posts under very different conditions from those that obtain to-day These older men were selected by a few large ratepayers who generally constituted what was known as the dispensary committee. These committee-men were all personally acquainted with the candidate. But the Local Government of Ireland Act of 1898 has altered all this. The dispensary committees have been dissolved and the appointments are in the hands of the entire boards of guardians. Therefore the dispensary medical officer is now dependent on men who had nothing to do with his appointment, many of whom, perhaps most of whom, he does not know. It may also happen that some of the guardians live far away, at distances of even 20 or more miles, for some of the rural Poor-law unions cover a very large though sparsely inhabited area The democracy governs much more than it did in the past and to a large extent consists of very ignorant poor cultivators and country folk, together with a few village tradesmen. These people vote at the elections and select from their own ranks guardians of the poor. They are not likely to understand the position and requirements of medical men.

Whether it be that medical men in Ireland are more active politicians than in England, there certainly does not seem to have been any particular hesitation shown in adopting the ways and methods of the ordinary electioneering agents. Indeed, I am told that some of the less creditable manœuvres were sometimes employed to secure an appointment. The Irish Medical Association, however, has endeavoured to teach the electorate that it was to their interest to secure the services of really competent and able medical men, adding that this could not be done unless the terms were such as would free the medical attendant from all money anxiety and trouble. The dispensary medical officer must feel secure in his position and know that he will not be left to starve in his old age. At present the pension is given as a favour, not as a right, and the guardians like to hold the dispensary medical officer under control by the threat that they may refuse to grant him a pension. This is undoubtedly a very great evil. Nevertheless, the electors are beginning to understand that it is to their advantage to secure the services of a really good medical officer, but they do not like giving pensions to officers whom they did not themselves appoint and whom they hardly know. In the south and east of Ireland the dispensary medical officers are better treated, and the North Dublin Union recently granted full pensions to two dispensary medical officers, though they were both of them Protestants. Then, again, there was a young dispensary medical officer who became the victim of a spinal disease. At first he was replaced by a locum-tenent but as his case became hopeless he had to resign. An agitation was started in favour of granting him a pension. Strictly speaking, he had served so short a time as not to be entitled to any pension, but the Irish Medical Association and the guardians persuaded the Local Government Board for Ireland to sanction the pension. In the north of Ireland, where Protestant is dealing with Protestant, there is less liberality shown. Perhaps this essentially commercial population has a keener relish for driving a hard bargain; in any case a Protestant board of guardians was mentioned to me which refused to give a pension to its dispensary medical officer, though he had served for 40 years. It is essential that the pension question shall be regulated by law and not depend on the fancies, the likes, or dislikes of a board of guardians. Then, and this is far more difficult, there should be a clear definition of what is meant by the term "a poor person," so that dispensary medical officers should no longer be called upon to attend gratuitously on patients who can well afford to pay medical fees.

The Irish Medical Association is also endeavouring to bring about a radical reform in regard to the sanitary administration of the country. Excepting in the large towns it may be said that there is no sanitary control in Ireland. In the country districts medical officers of health are appointed at merely nominal salaries. Very often the dispensary medical officer is given the post with an extra £10 a year. Of course, there is little or nothing that he can do. If he really attempted to enforce the existing sanitary laws he would be constantly prosecuting those who, by their votes, had given him his appointment and on whose votes he will again depend when the time arrives for him to retire and to ask for a pension. Therefore it is proposed to unite several sanitary districts into a smaller number of larger districts. Then it might be possible to employ at much larger salaries medical officers of health who would not need private practice, who would not be so dependent on local patronage of one form or another, and who could do their duty without fear or hindrance. This would, of course, include the prevention of the adulteration of food. In this respect nothing is done in the poorer rural districts. Diseased meat and all sorts of adulterated foodstuffs can be sold without interference and the law remains a dead letter.

The Irish Medical Association is also anxious to see that medical practitioners receive proper fees when called upon to give attendance under the Workmen's Compensation Act. Further, the association is endeavouring to get improved conditions for the medical staff of the Post Office and of the prisons. So it will be seen that there is much to do and that the association is not allowing the grass to grow under its feet. Then there are the usual professional cases and what this means may be judged by the fact that one of these cases lasted four years. It was in the early portion of the year 1902 that a medical officer was dismissed from the constabulary and the Irish Medical Association thought such dismissal unjustifiable Protests were raised, petitions were drawn up, and a long correspondence ensued. The discussion was commenced in the locality and gradually reached Dublin Castle and the Royal College of Surgeons. Numerous inquiries were instituted and finally, after four years of agitation, the surgeon in question was reinstated and the Irish Medical Association carried its point, saving one of its members from ruin. Doubtless this organisation will continue to prosper. In its ranks Catholics and Protestants seem to forget their religious and political differences, and this is an excellent sign not only for the prospects of the medical profession but for the pacification and happiness of the entire country.

The After-care Association.—Two important meetings have just been held on behalf of this association, the object of which is to assist the readmission into social life of poor persons who have been discharged recovered from asylums for the insane. At one of these, which took place at New Southgate, the Bishop of Islington was in the chair, and the meeting was also addressed by Dr G F. Blandford, Dr. W. J. Seward, the Rev. F. Hall, the Rev. F. H. A. Hawkins, and Mr. H. Thornhill Roby. The second meeting was held at The Elms, Chelmsford. The High Sheriff of Essex presided and the speakers included the Bishop of Colchester, Dr. G. H Savage, Dr. G. Amsden, and Mr. H. Thornhill Roxby, the secretary of the association. A good collection was made and several new subscriptions were promised. The number of cases assisted by the association during the present year shows an increase over those of any previous years and several branches are being formed in connexion with various asylums in different parts of the country. The offices are at Church House, Dean's Yard, Westminster, London, S.W., and the association's bankers are the Union of London and Smiths Bank, Limited, Argyll-place, London, W.

Frederick Thatcher, Scotland; § Charles August Thelander, Australia; Charles Petrus Theron, B.A., South Africa; § David Thomson, Scotland; William Thomson, Scotland; William Wilson Thomson, Scotland; Arthur Lincoln Thornley, England; Frederick John Gordon Tocher, Scotland; Lydia Knight Towers, Scotland; Martha Beatrice Webb, England; John Clarkson Birkbeck Williams, England; David James Williamson, England; ‖ James Leitch Wilson, Scotland; and James Ley Masterman Wood, England.

§ Passed with first-class honours.
‖ Passed with second-class honours.

Bachelor of Science in the Department of Public Health.—Matthew Bernard Burton, M.B., C.M.

Diploma in Tropical Medicine and Hygiene.—Archibald Guelph Holdsworth Smart, M.B., Ch.B.

The following Fellowships, scholarships, and prizes have been awarded :—

Goodsir Memorial Fellowship, James Lochhead, M.A., B.Sc., M.D., Ch.B.; Syme Surgical Fellowship, James Walker Dawson, M.B., C.M. (*in absentiâ*); Milner Fothergill Medal in Therapeutics, James Andrew Gunn, M.A., B.Sc., M.D., Ch.B.; Gunning Victoria Jubilee Prize in Anatomy, Alexander Ninian Bruce, B.Sc.; Gunning Victoria Jubilee Prize in Chemistry, Alexander Thomas Cameron, M.A., B.Sc.; Ellis Prize in Physiology, William Cramer, Ph.D., D.Sc.; Ettles Scholarship, Robert Hillhouse Jamieson, M.B., Ch.B.; Allan Fellowship in Clinical Medicine and Clinical Surgery, John Fraser, M.B., Ch.B.; Freeland Barbour Fellowship, Robert Hillhouse Jamieson, M.B., Ch.B.; Buchanan Scholarship in Gynæcology, Albert Edward Bennee, M.B., Ch.B.; James Scott Scholarship in Midwifery, David Lees, M.A., M.B., Ch.B.; Mouat Scholarship in Practice of Physic, Dewan Hakumat Rai, M.A., M.B., Ch.B. Murchison Memorial Scholarship in Clinical Medicine, James Sutherland Edwards, M.B., Ch.B. M'Cosh Graduates and Medical Bursaries, Douglas James Guthrie, M.B., Ch.B., and John Howard Horne, M.B., Ch.B. (equal). Beaney Prize in Anatomy and Surgery, John Howard Horne, M.B., Ch.B. Conan Doyle Prize, Albert Edward Bennee, M.B., Ch.B. Dorothy Gilfillan Memorial Prize, Helen Meldrum M'Millan, M.B., Ch.B. Wightman Prize in Clinical Medicine, Alexander Gibson, M.A.; and the Anderson Henry Prize in Botany, John William Bews, M.A., B.Sc.

UNIVERSITY OF ABERDEEN.—The following degrees and diploma have been conferred :—

Degree of Doctor of Medicine (M.D.).—William Campbell Anderson, B.Sc., M.B., Ch.B., London; † Robert Brown, M.B., Ch.B., London; † James Clark, M.B., Ch.B., Maryport; * Frederick William Ellis, M.B., Ch.B., London; Maurice Buchan Johnson, M.B., Ch.B., Bedford; * Peter Macdonald, M.A., M.B., C.M., Acomb (under old regulations); and William Mitchell Smith, M.B., C.M., Tean, Stoke-upon Trent (under old regulations).

Degree of Master of Surgery (Ch.M.).—Alexander Mitchell, M.A., M.B., Ch.B., Old Rayne, Insch.

* Commendation for Thesis. † Honours for Thesis.

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) (New Ordinances).—With Second Class Honours: Walter James Dilling, Aberdeen; *David Horn, B.A., Toowoomba, Queensland, Australia; George Henry Charles Lumsden, Aberdeen; James Milroy M'Queen, M.A., B.Sc., Aberdeen; Andrew M'Kay Niven, Aberdeen. Ordinary degree: Ernest Edward Allaway, Woodhouselea; John Webster Archibald, Kimberley, South Africa; Thomas Clapperton, Potterton, Whitecairns; John Ferries, Harthill, Countesswells; William Ingram Gordon, M.A., U.F.C. Manse, Pluscarden; Alexander Horn, Toowoomba, Queensland, Australia; John Elrick Kesson, Aberdeen; Benjamin Knowles, Aberdeen; James Leask, Elgin; Margaret Cameron Macdonald, Dingwall; Dalziel Buchanan M'Grigor, Culter; William Ian Mackintosh, Invergarry; James Moir Mathieson, Stonehaven; James Aberdein Milne, Aboyne; Benjamin Mitchell, Whitecairns; James Mitchell, Aberdeen; John Murray, Kincardine-O'Neil, Algernon Edgar Cyril Myers, Port Royal, Jamaica; Patrick Nicol, Aberdeen; Arthur Shepherd, Shethin, Tarves; *Alexander Stewart, Murtle; William Lemmon Stewart, Aberdeen; and John M'Intosh Wilson, M.A., Aberdeen.

* Awarded the John Murray medal and scholarship.

Diploma in Public Health.—Arthur George Troup, M.B., Ch.B. Aberd., Aberdeen.

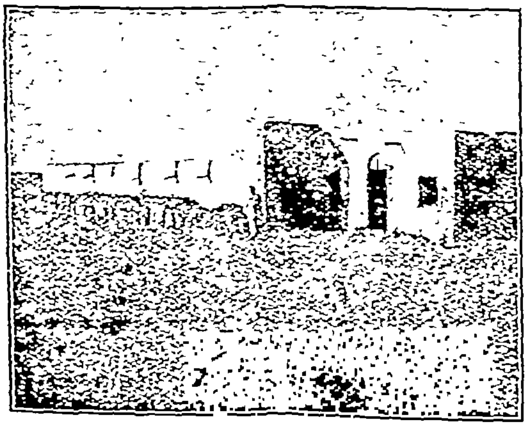
FOREIGN UNIVERSITY INTELLIGENCE.—*Copenhagen:* Dr. O. F. Jacobsen has been recognised as *privat-docent* of Internal Medicine.—*Heidelberg:* Dr. Hermann Euler has been recognised as *privat-docent* of Odontology.—*Moscow:* Dr. Golubinin has been appointed Extraordinary Professor of Therapeutics.—*Munich:* Dr. Rudolf Grashey has been recognised as *privat-docent* of Surgery.—*Philadelphia (Jefferson Medical College):* Dr. J. H. Gibbon has been appointed to the chair of Surgery.—*Tubingen:* Dr. L. Merzbacher has been recognised as *privat-docent* of Psychiatry.

CALEDONIAN MEDICAL SOCIETY.—The twenty-seventh annual meeting of the Caledonian Medical Society was held in the Royal Eye Hospital, Bradford, on July 25th. Dr. Andrew Little presided over a large and representative gathering of members from both sides of the border. He took for the subject of his presidential address "The Life and Work of the late John Henry Bell of Bradford." Dr. J. Keay, physician superintendent of the Edinburgh District Asylum, Bangour, was elected President for next year. The annual dinner was held at the Midland Hotel, Bradford, on the same evening, when between 30 and 40 members and guests were present. The toast of "The Society" was proposed by Dr. G. I. Swanson of York and responded to by the President and honorary secretary. "The Scottish Universities" was proposed by Dr. W. Gordon Little (Blundellsands) and acknowledged by Professor H. J. Campbell of the University of Leeds. "Caledonia" was proposed by Dr. A. C. F. Rabagliati (Bradford) and responded to by Dr. H. Cameron Gillies of London.

CENTRAL MIDWIVES BOARD.—Special meetings of the Central Midwives Board under the provisions of Rule D 5 were held on July 18th and 19th at Caxton House, Westminster, Dr. F. H. Champneys occupying the chair. The Board considered the following charges amongst others against the midwives whose names are given below and ordered them to be struck off the roll:—Mary Jane Banks, that being in attendance at a confinement she attended with an open sore on her finger; that the perineum being seriously ruptured and the placenta not having been completely expelled an hour after the birth of the child she did not send for a medical man. Frances Box, that being in attendance as a midwife at a confinement, the perineum being seriously ruptured, she did not send for a medical man. Sarah Brettell, that being in attendance at a confinement she neglected to take any steps to secure the comfort or cleanliness of the patient during the lying-in period and persistently refused to permit a registered medical practitioner to be sent for though the patient frequently expressed a desire that one should be fetched. Annie Broomhead, that she was found drunk and incapable within half an hour after attending at a confinement. Mary Brown, that she personally undertook the management of presentations other than the uncomplicated vertex or breech instead of declining to attend alone and advising that medical help should be sent for as required by the rules, and that though unable to read a thermometer she persistently declined to receive instruction in that respect. Sarah Dawn, that she was uncleanly in her person, clothing, house, and appliances, and that on March 19th, 1907, she was drunk while on duty as a midwife. Rebecca Ann Gill, that being in attendance at a confinement a medical man having been sent for to deliver the patient and another medical man having subsequently been sent for to attend the patient, she failed to notify the same to the local supervising authority as required by the rules; and that on March 22nd, 1907, she refused, without reasonable excuse, to allow the inspector of midwives to enter her house or to inspect her appliances and register. Jane Heath, that having been duly suspended from practice as a midwife by the local supervising authority she nevertheless, while under suspension, attended and acted as a midwife at confinements and that ante-partum hæmorrhage occurring in one of these cases she did not send for a medical man. Jane Perkins, that being in attendance at a confinement the death of the child having occurred before the attendance of a registered medical practitioner, she failed to notify the death to the local supervising authority and she attempted to get the child buried as still-born, well knowing that it had been born alive. Eliza Southall, that being in attendance at a confinement, the presentation being a shoulder one, she did not send for a medical man. Ellen Anders, that being in attendance at a confinement, the progress of the patient after delivery not being satisfactory, she did not send for a medical man and discontinued her attendance on the fifth day. Ellen Birkett, that being in attendance at a confinement on March 8th, 1907, she neglected to cleanse the infant's eyelids on birth; that she neglected to remove the soiled linen from the neighbourhood of the patient but left it lying under the bed; and that the child's eyes being inflamed and discharging on March 12th she did not send for a medical man. Charges were heard against the following midwives and their names were ordered to be struck off the roll: Sarah Ann Blackledge, Sarah Ann Chapman, Catherine Hawkins, Margaret Kirby, Margaret Riding, Mary Jane White, Mary Ellen Darlington, Jane Annie Gambrill, Jane Rayne, and Mary Ann Freedom Wilkinson. The following midwives were cautioned by the Board after charges alleged against them had been considered: Kate Martin, Ann Robinson, and Katherine Wraith. ——An ordinary meeting was held at Caxton House, Westminster, on July 25th, Dr. F. H. Champneys being in the chair. A letter from the solicitor to the London County Council was read reporting the conviction of Mrs. Ita Feldmann for unlawfully using a description implying that she was specially qualified to practise midwifery. A letter from the could nevertheless also be employed for returning pilgrims as the old lazaret had been; and that finally the new project had been sanctioned by Iradé. Notwithstanding this declaration no practical steps were taken to carry out the project. From time to time the opinion has been expressed that a lazaret such as that foreshadowed in the above declaration ought to be created somewhere near the northern end of the Red Sea. There would be many practical difficulties, however, in the way of carrying out such a proposal, more particularly in finding a suitable site. El Wej has been shown by experience to be wholly unsuited for the purpose and no other site has been seriously recommended. Moreover, shipping would to some extent suffer since pilgrim ships would be compelled to lie at the new lazaret during the whole period of quarantine in order to re-embark their pilgrims and to carry them to the Hedjaz, whereas under present conditions they take the pilgrims straight to the Jeddah (Abu-Saad) lazaret, land them there, and are then free after disinfection to return and to start a fresh voyage. There would, indeed, be no need to consider the possibility of creating yet another lazaret were that at Abu-Saad large enough to receive all pilgrims from the north when they are subject to quarantine. But, as pointed out in Article X. of this series, the most satisfactory solution of that difficulty would be the enlargement of the Abu-Saad lazaret by means of an annexe on the mainland in the neighbourhood of the islands upon which it is now built.

The small town of El Wej is rather attractively situated: the cliffs rise here to a height of some 50 or 70 feet, and the houses are built partly on the shores of the bay and partly on the cliffs. A large oasis, studded with palms and other trees, runs inland behind the town. Water is more abundant here than at Yanbo or Jeddah. The town has a Kaimakam or Turkish governor and a small garrison of soldiers is stationed here. On the south side of the bay is a high tower, apparently once a light-house, and at no great distance from this are the ruins of the lazaret. One large, roofless building remains the walls of which are slowly crumbling to pieces. It is shown in Fig. 39. At its back are the vestiges of a masonry reservoir, cemented inside some 20 yards long, five wide, and two deep. It was evidently intended to store drinking water. A short distance away is what remains of a stone landing jetty which is in a better state of preservation than the building just described. Near the northern shore of the bay there rises out of the water a black and monstrous object which looks strangely out of keeping with its surroundings; it is the relics of the distilling apparatus that once furnished the lazaret with water and the bursting of which led to the final abandonment of El Wej in favour of El Tor. The barge, or pontoon, on which it floated appears to have sunk or been run ashore. Portions of it can be seen above water, but the bulk of the black mass is formed by the iron shell of the distilling apparatus itself which still keeps its form in spite of 30 years' exposure to sun and wind and damp. (Fig. 40.)

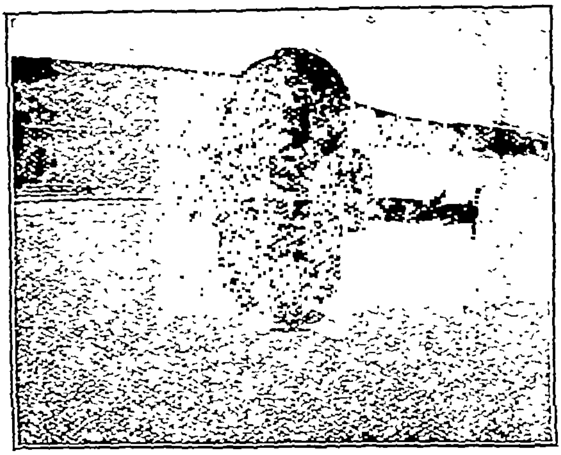
FIG. 39.



El Wej: remains of the lazaret.

With these brief notes of an extinct, and almost vanished, lazaret the present series of articles must close. It had when starting to write them, to include a description of the other sanitary institutions visited by the Inspection Commission, notably the lazaret of Beirût and the disinfecting stations recently established at Jaffa and Rhodes. But, apart from considerations of space, these articles may be fittingly limited to a description of some of the Red Sea lazarets and the part they play in the control of disease extension in connexion with the pilgrimage to the Hedjaz. To describe the three institutions just mentioned would be to enter the Mediterranean and to touch upon the very much larger question of the network of sanitary defences at the eastern end of that sea, of which those institutions only form a small portion.

FIG. 40.



El Wej: the abandoned condenser and barge.

It should be added, however, that the foregoing articles have by no means exhausted the list of sanitary defences even of the Red Sea. There is a small lazaret at Aden; a new one has just been created at Perim; there is one at the Italian port of Massowah, another at Suakim, and a very large one at El Tor, on the Sinaïtic peninsula. The last two are under the administration of the Alexandria Sanitary, Maritime, and Quarantine Board. To deal, indeed, at all adequately with the entire system of international prophylaxis in the Red Sea alone, as it is carried out by the two boards of Constantinople and Alexandria respectively, would require a much longer series of articles than the present one. If these chapters, however, have succeeded in giving their readers some idea of the large and costly institutions which, under the name of lazarets, have been brought into existence under international auspices as the main instruments of that prophylaxis, as also of the many and complex problems which the two boards just named are called upon to solve—not only in connexion with the pilgrimage, but also in connexion with the entire sanitary defence of the Near East—they will not have been written in vain.

Constantinople.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Professorship of Medicine.

As recorded in the last issue of THE LANCET Dr. Graham Steell has been appointed by the Council professor of medicine in the University of Manchester. In Dr. Steell the high standard kept up by the former incumbent of the professorship of medicine will be fully maintained. Clear and concise in diction, his teaching is accepted as the outcome of accurate, clear-sighted, clinical observation. His writings have been largely concerned with the diseases of the lungs and heart and his recently published text-book on the latter subject will enhance the reputation which he has already acquired. But it would be a mistake to consider Dr. Steell as a lung and heart specialist to the neglect of the other branches and he will be found an able and learned exponent of the science and art of medicine.

The Pharmaceutical Conference.

The forty-fourth annual meeting of the British Pharmaceutical Conference has just been held in Manchester. The school children, the *Vaccination (Scotland) Bill*, and the Public Health (Scotland) Bill. He then came to the Bills which the Government was resolved to proceed with. These included the *Butter and Margarine* Bill, the Probation of Offenders Bill, *the Vaccination Bill*, and the Public Health (*Regulations as to Food*) Bill.

Bills Advanced.

The Butter and Margarine Bill, the *Probation of Offenders Bill*, and the Vaccination Bill were all *considered and read a third time.*

Bills Withdrawn.

The orders for the second reading of the *Poisons* and *Pharmacy* Bill and the Municipal Milk *Depôts Bill* were discharged and the Bills were withdrawn.

The Royal Commission on Tuberculosis.

The Royal Commission on Tuberculosis has presented *to Parliament* a large volume of evidence relating to experiments bearing *on the* pathogenic effects of bovine viruses.

HOUSE OF LORDS.

WEDNESDAY, JULY 31ST.

Public Health (Scotland) Amendment Bill.

Lord HAMILTON of DALZELL, in moving the second reading of the Public Health (Scotland) Amendment *Bill*, explained that certain clauses in the Public Health (*Scotland*) *Act of* 1897 had been found to be unduly restrictive in *the* case of the milder infectious diseases, and there was no *doubt* they would be found to be absolutely intolerable if they were applied to consumption. It was believed that it was this fact which *had prevented the local* authorities from including consumption in the list *of notifiable diseases although, on* other grounds, they were fully aware of the desirability of doing so. Certain relaxations of the existing law were, therefore, provided in the Bill and a certain discretion was left to the medical *officer as to* what adequate precautions should be taken.

Lord BALFOUR of BURLEIGH expressed approval *of the measure.*

The Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, JULY 24TH.

Infectious Disease in Schools.

Mr. G. J. COOPER asked the President of the Board of Education whether *his attention had been drawn* to the exclusion, from *September*, 1906, *to the present date*, of Ellen and Edward *George from the Rolls-road* London County Council *school* on the ground *that they were suffering* from ringworm; *whether* the certificate excluding these children from school *was signed by a nurse*; whether he was aware that, *on the children being taken to* the London Hospital for *treatment the parents* were told that the children were not suffering from ringworm but steatorrhœa, a non-infective disease; whether, although the *parents* had given the teacher a certificate complying with Section C, Sub-section 10, *Article* 3 *of* the School Management Code, the children *were still refused* admission; whether this exclusion was in *opposition* to the wishes of the managers of the school, who were anxious that the children should return; whether the nurse on whose certificate the children were excluded possesses any medical qualification; if not, *whether a medical* certificate given by an unqualified person could exclude a child from school; and whether his department proposed to take any, and, if any, what, action in the matter.—Mr. McKENNA furnished the following written answer: The Board of Education has no *information* as to the incidents referred to. In *the event of an* appeal being made to it on the ground that the children have been excluded from school on other than reasonable grounds the circumstances will be carefully investigated before a decision is arrived at.

THURSDAY, JULY 25TH.

International Congress on School Hygiene.

Dr. V. H. RUTHERFORD asked the President of the Board of Education whether he was aware of the fact that several foreign *powers could not* see their way to send delegates to the Second International Congress on School Hygiene to be held in London next month unless they received invitations from His Majesty's Government; and whether, in the interests of international goodwill and also of education, both in this country and throughout the world, *His Majesty's Government* would issue official invitations and *so insure the* success of the Congress.—Mr. LOUGH (*who replied on behalf of* Mr. McKENNA) said: No, sir, I have received no authenticated *official information* that any *foreign Governments* have *abstained from* sending official representatives to the *Congress* for the reasons alleged in the question. I have verified from official sources that at least one of the *principal European* Governments, in respect *of* which *the allegation is made, is in fact* sending official representatives *to the Congress*, having apparently felt no difficulty as to the invitation, so that in its case the allegation must be unfounded. I have heard no *suggestion* except as part of the allegation above referred to, that any other *Governments* have felt differently in this respect. As to the last paragraph of the question, in view of the facts I have ascertained, as above explained, I have nothing to add to the answer my right honourable friend gave last week *to the* honourable *member for* Leicester.

The Medical Bureau of the Board of Education.

Mr. BRIDGEMAN asked the President of the Board of Education whether any estimate had been prepared as to the cost of salaries and administration of the medical *bureau which it was* proposed to appoint under the Board; and whether such bureau would *supervise medical* questions which might arise in Welsh schools.—Mr. LOUGH (*who* answered on behalf of Mr. McKENNA) said: *The matter is now under* my right honourable *friend's consideration* in consultation with the Treasury. The answer to the second paragraph is in the affirmative.

Inoculation for Plague.

Mr. JOHN ROBERTSON asked the Secretary of State for India whether, *in view of the fact that* inoculation for plague in the Punjab of late had been resorted to in increasing numbers of cases and *that the death-rate from plague* was there at the highest, he would take into consideration the expediency of abandoning the practice as dangerous.—Mr. MORLEY replied: The opinion of those who have had experience *is* that the health of the *patients* is unimpaired by inoculation, *even where they* are children *of poor* constitution; and that it confers immunity of from six to 12 months *or* more. Statistics in Bombay show in the case of municipal *labourers that while the* percentage of uninoculated who were attacked *by plague* was 6·7 that of the inoculated was *only* 0·19.

MONDAY, JULY 29TH.

Medical and Nursing Assistance in the Highlands.

Mr. CATHCART WASON asked the Secretary for Scotland whether he was aware of *the fact* that the Congested Districts Board was precluded from in any way assisting the poor people of the Highlands and Islands in *respect of medical* and nursing assistance; that there were islands and *districts far distant from any* possible medical and nursing assistance; and whether, in *view of* the fact that the position of the Congested Districts Board *was now under* consideration, he would consider the desirability of extending its powers or the powers of any body that *might succeed it.*—Mr. SINCLAIR replied: My honourable friend is correct in stating that the existing powers of the board do not extend to the purposes *referred to.* I am aware that the resources of the authorities responsible for public health in certain districts are slender and *I do not think that the extension of powers* to the Congested Districts Board is *a way of meeting the difficulty.*

TUESDAY, JULY 30TH.

A Vaccination Case at Croydon.

Mr. LUPTON asked the President of the Local Government Board whether he was aware that the boy who died in Croydon on April 29th last and whose case was investigated by Dr. S. M. Copeman of the Local Government Board, only broke out into sores about a week or ten days after vaccination, and that it was in *order to cure* these sores that the public vaccinator prescribed bromide treatment; and if this were so whether he would refer the question of the safety or otherwise of calf lymph to a Committee of the House or a Royal Commission.—Mr. JOHN BURNS answered: I do not understand the *facts* are as my *honourable* friend supposes. I am informed that the child was unsuccessfully vaccinated on Jan. 4th and successfully on the 11th of that month. The sores seem to have first appeared on Jan. 24th, whilst the bromide was first administered on Jan. 7th. It will be seen therefore that *the administration* of bromide commenced before the sores *made their appearance*. I do not understand that it was prescribed in order to cure the sores. It seems to have been suggested as a remedy for the fits from *which the child* suffered.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.*

BENSON, E. G. D., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Stanley District of the county of Durham.

BOWMAN, G. F., M.B., M.Ch. Vict., has been appointed Medical Officer of Health by the Limehurst Rural District Council.

BROWN, ALFRED AUSTIN, M.B. Melb., has been appointed Inspector of Food for Export, Department of *Agriculture*, Victoria, Australia.

FETHERSTONHAUGH, ROBERT TREVOR, M.R.C.S., M.B. Melb., L.R.C.P. Lond., has been appointed Acting Port Health Officer (*pro tem.*) for the Port of Geelong, Victoria, Australia.

GOULD, H. U., *M.B.*, *B.S. Cantab.*, has been appointed Certifying Surgeon under the Factory and Workshop Act for the Shaftesbury District of the county of Dorset.

HAWKSLEY, W. L., M.B., Ch.B., D.P.H. Liverp., has been appointed *Assistant* Medical Officer at the New City Hospital for Infectious Diseases, Fazakerley, Liverpool.

HOLLICK, B. S., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the *Sturminster* Newton District of the county of Dorset.

LEWIS, WILLIAM JAMES, L.R.C.P. & S., L.M. Edin., L.F.P.S. *Glasg.* has been appointed Medical Officer of Health by the *Pontardawe* (Glamorganshire) Rural District Council.

SPOWERS, E. A., M.D., Ch.B. Melb., has been appointed Honorary Gynæcologist to Out-patients and Assistant *Gynæcologist* to In-patients at St. Vincent's Hospital, Victoria, Australia.

WEBB, ARTHUR BRIDGES, M.B., Ch.B. Melb., has been appointed Medical Officer *of Health for the Shire* of Grenville, *Victoria*, Australia.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARROW-IN-FURNESS, NORTH *LONSDALE* HOSPITAL.—House *Surgeon.* Salary £100 *per annum*, with board and lodging.

BATH, BAILBROOK HOUSE.—Medical Superintendent. *Salary* £350 per annum, with extra payments, board for *self and wife* if married, quarters, laundry, and attendance.

BIRMINGHAM, QUEEN'S HOSPITAL.—House Physician. Also *Obstetric* Ophthalmic House Surgeon for seven *months*. Salaries at the rate of £50 per annum, with board, lodging, *and* washing.

BOURNEMOUTH, ROYAL VICTORIA *HOSPITAL.*—House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

BRIDGNORTH AND SOUTH SHROPSHIRE INFIRMARY.—House Surgeon. Salary £100 per annum, with board and lodgings.

BRIGHTON, *HOVE, AND PRESTON* DISPENSARY.—House Surgeon. Salary £160, with *rooms*, coals, gas, and attendance.

BUXTON, *DERBYSHIRE*, DEVONSHIRE HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with apartments, board, and laundry.

was formally opened. The cost of the apparatus was about £350 and the department will be under the direction of Dr. J. Delpratt Harris. A memorial tablet recording the opening of the department was unveiled by Lady Duckworth-King.

July 30th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Edinburgh: Graduation Ceremony.

THE summer graduation ceremony at the University of Edinburgh was held on Friday, July 26th. The Vice-Chancellor, Principal Sir William Turner, presided. Before the candidates for medical degrees were presented Sir Ludovic Grant presented the name of William Bayard, M.D., St. John, New Brunswick, for the honorary degree of LL D. In doing so it was stated that, so far as was known, Dr. Bayard was the "patriarch of the whole vast tribe of Edinburgh graduates throughout the world." He graduated in 1837, and although 93 years of age is in vigorous health and still practising his profession. It was not, however, on account of his longevity alone that Dr. Bayard had been deemed worthy of academic recognition—"yet higher grounds were furnished by the rare wisdom, the probity, the dignity, and nobility of character which he had ever displayed in the practice of his profession and in social intercourse. He had long exercised by virtue of these qualities a salutary and ennobling influence amongst his medical brethren in New Brunswick, while by the entire community there he was greatly honoured and greatly beloved." Sir J. Halliday Croom presented the ordinary medical graduates. For the degree of M.D. 69 candidates were presented. Gold medals for theses (the subjects of which are appended) were awarded to Dr. Lesley Newton Hesketh Biggs, India (the Perfusion of the Mammalian Heart with Locke's Fluid, and Investigation of the Bundle of His): Dr. James Andrew Gunn, Scotland (a Contribution to the Pharmacology of Yobimbine); Dr. James Lochhead, Scotland (Some Problems of Fœtal Nutrition, with special reference to the Function of the Placenta); Dr. Stuart McDonald, Scotland (the Pathology of Epidemic Cerebro-spinal Meningitis); Dr. Hugh Angus Stewart, Scotland (Experimental and Clinical Investigation of the Pulse and Blood Pressure Changes in Aortic Insufficiency); and Dr. Henry Wade, Scotland (a Contribution to the Problem of Cancer Research Based upon the Results of an Experimental Investigation of Infective Sarcoma of the Dog). The degree of Master of Surgery was conferred on two candidates The degrees of M.B., Ch.B. were conferred on 119 candidates, including three women. The diploma in Tropical Medicine and Hygiene was conferred on one candidate. The Ettles scholarship was awarded to Robert Hillhouse Jamieson, M.B., Ch.B. When the degrees had been conferred Sir Halliday Croom addressed the graduates. After the ceremony was concluded a house luncheon was held in the University Union when it was intimated that the sum of £6000 had been raised which entitled them to a like sum from Mr. Carnegie and from Sir Donald Currie, so that their buildings were paid for.

Enteric Fever at Peterhead.

According to the report of the medical officer of health the total number of cases of enteric fever notified so far has been 250. During the past week 24 cases were reported, as compared with 33 in the preceding week. It is estimated that about 100 cases have fully recovered. The total number of cases treated in the hospital has been 75, 16 of which have been dismissed well.

Condition of the Fish-curing Yards in Aberdeen.

At the last meeting of the public health committee of the Aberdeen town council attention was drawn to the statement made in the House of Commons last week with reference to the satisfactory condition of the fish-curing yards in Aberdeen, and gratification was expressed in the committee that public notice should be taken of this in view of the activity of the sanitary officers.

Royal Army Medical Corps: Aberdeen Companies at Barry.

Contrary to what has been the case during the past few years the corps has remained in Scotland for its annual camp training. On June 28th about 170 men left Aberdeen for Barry under the following officers: Captain Fraser, Captain Rorie, Captain Wallace Milne, Lieutenant Innes, Lieutenant Howie, Quartermaster Cromar, and Chaplain the Rev. Jas. Smith. Colonel T. M. Corker, principal medical officer of the Scottish district, has visited the camp and inspected the men. He expressed himself as being very pleased with the condition in which he had found men and stores.

Pharmaceutical Conference in Aberdeen.

The British Pharmaceutical Conference met in Manchester this week and on the invitation of the representatives of the Pharmaceutical Association of Aberdeen and the North of Scotland it was decided to hold its meeting next year in Aberdeen. Officers were elected for the ensuing year, Mr. R. Wright of Buxton being made President.

Inverness Infirmary: Gift of a Ward for Consumptives.

A special meeting of the Inverness Infirmary managers was held on July 25th, Baillie John S. Fraser presiding. A letter was read from Dr. Mackay intimating an offer from an anonymous gentleman of £1000 or £1200 to provide a ward for isolating and specially treating consumptive patients in the Northern Infirmary. Mr. Shaw moved that the offer should be accepted and that it should be remitted to a committee to ascertain the cost of the proposed ward and to report, and this was agreed to.

July 27th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Belfast Health Commission.

ON July 22nd several officials, a lodging-house inspector, and the superintendent of markets having been examined, Mr. H. C. Manley, dispensary medical officer of Whitehouse, on the western side of Belfast Lough, gave evidence as to his district. He said that the sanitary condition of Greencastle was far from satisfactory. In reply to one of the Commissioners (Dr. L. W. D. Mair) Mr. Manley said that the nuisance caused by sea-weed (ulva latissima) at Lower Whitehouse was terrible. He also said that people came to this part of the shore in crowds to collect cockles. On that very morning he had seen a large number of people arriving from the shore with bags of mussels and cockles. Such a practice, he thought, should be put a stop to. The new veterinary surgeon of the corporation (Mr. J. A. Jordan), who was appointed three months ago, said that the number of seizures of unsound meat in the city was not large. If the whole carcass of an animal was affected it was seized and destroyed, but if the tuberculosis was purely local the part affected was removed and the carcass was allowed to pass. He had no power to inspect cattle outside the district. He did not consider that the surroundings of the abattoir were good. The city surveyor having given further evidence as to the sewage outfall, the engineer-in-chief to the Harbour Commissioners produced maps and photographs in connexion with the much discussed chute through which the city sewage passes into the sea in Belfast Lough. The medical superintendent officer of health having been further examined the chairman of the public health committee referred to the reforms and improvements which had been effected by the corporation in regard to the drainage of the city and other matters. Mr. W. McGrath, K.C., addressed the Commission on behalf of the corporation, his main point being that the Registrar-General had not allowed for the increase in the population and that as a result the death-rate was reckoned as too high. He said that if the reforms suggested by the bodies which indicted the corporation were to be carried into effect it would mean increased expense to the ratepayers. The chairman of the public health committee having on behalf of the corporation given expression to its sense of the great ability, thoroughness, and patience with which the inquiry had been conducted, Sir John Byers said that on behalf of the medical profession he would like to endorse what had been said regarding the exceedingly thorough, careful, and fair manner in which the Commissioners had tried to elicit the truth in that inquiry. The members of the medical profession had no personal interest in the matter. All they wished to do was to try to bring the city, so far as public health was concerned, up to the standard of other large cities in England and Scotland. Mr. G. W. Ferguson, on morning; if these small doses are steadily persevered with improvement gradually results.

3. Mr. Penrose Williams recommends a pill *containing one-sixth of a grain* each of calomel and extract of belladonna and two grains of confection of senna, to be taken two, three, or four times a day.

4. Mr. J. Hopkins Walters writes that if the *colotomy* is left-sided the case would be appropriate for appendicostomy, which *would enable the bowel to be washed out daily* and would make aperients unnecessary.

5. Dr. J. Cropper *recommends an enema of cold or tepid water* slowly introduced into the bowel before breakfast, varied in amount from one-quarter to three-quarters of a pint. This will produce a soft motion in an hour or two.

6. Dr. John Alcindor recommends faradisation of the abdomen from ten to 20 minutes every day, gentle massage of the abdomen daily, and a glycerine enema two or three times a week. Drugs should be avoided during the first week but in the second week ten minims of dilute nitrohydrochloric acid and from five to ten minims of tincture of *nux vomica may be taken three times a day* after food. In course of time the enemata may be gradually discontinued and sulphate of magnesium should be added to the prescription.

NO CREDIT AT THE ALL-NIGHT STATION.

THE *Kscob. Dnevnik*, commenting on the new medical station which is kept open day and night in Bratskoi-street, Warsaw, says:—"When an *urgent night call is telephoned to the station* the answer is that '*the cost of the call must* be paid at the station before the medical officer will start out. The station gives no credit.'" The editor of *our Russian* contemporary adds that "the Varsovians pride themselves on their Europeanisation"; but he does not know the conditions which prevail, at any rate, in this country. Our medical men are liable at all times and in all places to be summoned to the assistance of the public, and if a suggestion is made that a fee should be paid first their brutal attention to business is deeply resented. When the patient dies it is quite usual for the medical man *to find himself stigmatised by* a coroner's jury as a callous ruffian, the jury not even taking the trouble to find out whether the seriousness of the case was ever explained to the medical man. We are glad to say that coroners are beginning to recognise the gross injustice of this attitude towards medical men, and are directing juries to remember that medical men cannot work without meat and bread and *are not able to commandeer these* necessities but are *compelled* to pay for them. We are far, however, from the Varsovian position where the public is made to pay for its medical assistance on the spot, and as a matter of course.

A CORK PORCELAIN BOTTLE SEAL.

THIS consists of a ring of cork pressed on the lip of the bottle by means of a stout wire spring attached to a porcelain stopper. It provides a perfectly clean method of sealing the contents of a bottle, the only substance in contact with the liquid being a narrow strip of cork. Moreover, the sealing is effectual, for we examined a bottle containing ordinary soda water. The bottle was kept upright for some time under water when not a trace of *gas was observed to escape.* On liberating the *stopper the soda water was found to* be briskly effervescent. It is suggested that this system would offer considerable advantages for sealing milk and certainly less innocuous materials than clean glass and cork could scarcely be used. The specimen was *submitted to us by the* Non-conductor Cork Co., of 2, Rangoon street, London, E.C.

THE FATE OF A LION-TRAINER.

AN *unfortunate assistant to* a trainer of lions came by his death at a Gloucester theatre recently in circumstances which well illustrate the risks of such an employment. It appears that he had been left in charge of the animals and that he had attempted *to give* them some unauthorised training. One of the lions escaped into a dressing-room and in trying *to entice* the animal back he threw a chair at it, whereat it pounced upon him and mauled him so that he speedily succumbed to the injuries. In this instance the presence of a public audience did not add to the horror of the occurrence and the victim was apparently in some measure to blame for the lion's ferocious onslaught as the animal enjoyed the *reputation of having a good temper* in ordinary circumstances, but in a sense he was "*butchered to* make a Roman holiday," as his whole occupation depended upon the demand that there is for such perilous exhibitions. While there remains such a demand there will always be found courageous if stupid persons to supply the required performances and it must be conceded that they earn their living honourably if, as we think, foolishly, but it will mark an epoch of ethical advance in the nation that first refuses to supply an audience to witness their *entertainments.* We believe that the animals are nowadays trained humanely in most cases and we are even ready to grant that the feat of training them may entail the development of a few undoubted virtues in the trainers, but we cannot *admit that* the effect, if any, on the minds of those who witness performances with dangerous wild beasts is of an edifying nature and in consideration of the undoubted danger of these feats their suppression appears to be desirable.

LONGEVITY IN INDIAN GAOLS.

THE habitual criminals of India who spend the greater part of their time in gaols have a far better prospect of longevity than their congeners who respect the law and lead honest lives. Such at least is the *opinion of the writer of an editorial article* in a recent issue of the *Pioneer*, his *conclusion being based on an examination* of the vital statistics of the United Provinces. Even when allowance has been made, he adds, *for the fact that a large* proportion *of the prisoners* are in the prime of life and that there is no infant mortality to swell the returns, the figures are a striking record of the care *bestowed* on the health of the wrong-doers. During the *period under observation the free* population suffered badly *from malarial fever and also, in certain districts,* from famine, but in *the prisons* these fruitful causes of *mortality* were absent. In Lucknow city the death-rate was 50 41, in Allahabad 36 87, and in Bareilly 34 19, whereas in the several gaols of those places it did not in any case reach 10 per 1000.

TINNED FINGER STALLS.

THE *Halifax board of guardians has recently had* a most unpleasant *reminder of* the multitude of evils that may be covered by a brightly labelled preserving *tin. We learn from the Local Government Chronicle* that the master of the Halifax workhouse reported to his board that on opening a tin of apricots for use in the workhouse he found amongst the fruit seven rubber finger-stalls and two cotton ones "which had evidently all been used by the *persons* tinning the *fruit.*" The purveyors of this tin of fruit were communicated with on the matter. *Comment on such absolutely disgusting carelessness* would seem almost superfluous were it not *for the fact of the* number of finger-stalls found; surely it passes the range of probability that no less than nine should be accidentally deposited in one tin; the occurrence has the appearance of being a particularly nasty piece of mischief on the part of someone having access to the tin before it was closed. *It is not unlikely that some of the finger-stalls* may have covered septic wounds, and the possibility of a repetition of such an occurrence should be severely guarded against by the manufacturers.

ALUMINITH FIREPROOF CHINA.

Messrs. Else and Co., Limited, of 16, Crane's-buildings, Church-street, Liverpool, have submitted to us a small sample cooking-pan made of the above material. It has the same smooth, bright, white surface *as porcelain* and appears to be unattacked by acids and *to be free from* poisonous metals. The surface was not in the least corroded when touched with strong hydrochloric acid nor was any darkening produced when sulphuretted hydrogen was brought into contact with the aluminite. We should say that this material is excellently adapted for vessels destined to contain food or for cooking purposes. It is spotlessly white and presents a beautifully clean smooth surface.

◆

One Interested in the Case.—The matter is one for the medical officer of health and the sanitary authorities to deal with. Full information should be given to the officials.

D.P.H. will find year by year in the Students' Number of THE LANCET the *books recommended for public* health examinations. It is well, however, *to inquire as to the* curriculum at the particular university or corporation where the candidate intends to obtain his diploma. The demonstrators in practical work will give the best advice as to manuals.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Daily Telegraph, Scarborough Evening News, Standard, Cornish Times, Westminster Gazette, Liverpool Post, Manchester Guardian, Staffordshire Sentinel, Edinburgh Evening News, Dublin Telegraph, Manchester Weekly Times, Glasgow Herald, Leeds Mercury, Daily Chronicle, Gloucester Citizen, &c.*

case to the Wiesbaden branch of the Leipsic Medical Union, to which allusion has been made on several occasions in these columns, the result being that none of the local medical men applied for the appointment. The central committee of the union was also informed and advertised in all the medical journals and in the provincial newspapers that the appointment of medical officer to the Wiesbaden post-office was "blocked" by the union. This means that no member of the union may till further notice take the place of the dismissed member, and as almost all medical men of good professional standing belong to the union the Wiesbaden postal authorities will probably have considerable difficulty in obtaining a new medical officer.

Professor von Leyden's Successor.

His Excellency Professor von Leyden, the celebrated professor of clinical medicine at the University of Berlin and one of the leading consultant physicians of the metropolis, has resigned his professorship and will accordingly retire at the end of the summer semester. The medical faculty, which in cases of vacant ordinary professorships is entitled to nominate three candidates to the Government, proposed Professor Müller of Munich, Professor Krehl of Heidelberg, and Professor His of Göttingen. Both of the two first mentioned declined to remove to Berlin, a fact which was much commented on in the medical and lay press, because a professorship in the University of Berlin has advantages both as regards emoluments and also in other ways over professorships in the other German universities. The Government has therefore appointed Professor His who is a son of the celebrated anatomist and was born at Basle in Switzerland.

July 29th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Infectious Diseases.

THE outbreak of plague seems to have diminished, no cases having been reported since my last communication. A suspected case at Melbourne, isolated at the Plague Hospital, proved not to be plague. Diphtheria has been rather more prevalent in Victoria and Melbourne than usual. The number of cases reported for the whole State for the fortnight ending June 1st was 92, with one death, as against an average of 75, with three deaths. In Melbourne 60 cases with one death were reported, as against the average of 31 cases with two deaths. The accommodation at the Melbourne Infectious Diseases Hospital was insufficient for the cases and to meet the emergency the committee has erected three tents in the grounds. Scarlet fever is also prevalent in the suburbs of Melbourne, ten cases having been reported in two days at Newport. All the cases were promptly isolated and the schools were inspected. Another outbreak of typhoid fever has occurred at the Hospital for Insane at Kew, Melbourne. It was thought that the previous epidemic was due to contamination of the soil under the floors of some of the rooms. The floors were taken up and the soil was treated, but this fresh outbreak seems to discredit the supposed origin of the trouble.

Removal of a Health Officer.

What is regarded by the local municipal council of Newmarket as a high-handed and unwarrantable action by the Board of Public Health of Victoria was the removal of the local health officer by the Governor in Council in the following circumstances. Owing to the presence of typhoid fever in the shire the Board asked the local health officer for a report. The request was not complied with for six weeks, the health officer explaining that his time had been so fully occupied that he had been unable to collect the required information sooner. The Board then recommended the Governor in Council to relieve the health officer of his position under the provisions of the Health Act. It was admitted that the report when received was a very full and good one.

Medical Congress of Australasia.

The next session—the eighth—of the Australasian Medical Congress is to be held in Melbourne on Oct. 19th, 1908. Some time ago a strong organisation committee was appointed and it has completed its labours and made the necessary preliminary arrangements. The President is Professor H. B. Allen who holds the chair of pathology in the University of Melbourne and was the general secretary of second session held in Melbourne in 1889. Mr. G. A. Syme is treasurer and Dr. H. O. Maudsley is general secretary. The Governor-General, the admiral, the governors of all the States of Australia, and the governors of New Zealand and Fiji have accorded their patronage and the Premier and Government of Victoria have given their special countenance and support. The meetings will be held at the University. The congress has been divided into 11 sections and their presidents, vice-presidents, sectional committees, and secretaries have all been appointed. The following have accepted office as presidents of sections:—Medicine: Dr. G. E. Rennie, physician to Prince Alfred Hospital, Sydney. Surgery: Dr. B. Poulton, lecturer on surgery in the University of Adelaide and surgeon to Adelaide Hospital. Obstetrics and gynæcology: Mr. E. T. Thring, gynæcologist to Prince Alfred Hospital, Sydney. Anatomy and Physiology: Dr. J. T. Wilson, professor of anatomy in the University of Sydney. Pathology: Dr. F. Tidswell, director of the Bacteriological Laboratory, Board of Health, Sydney. Public Health and State Medicine: Dr. J. M. Mason, Chief Health Officer of New Zealand. Diseases of the Eye, Ear, and Throat: Dr. J. Lockhart Gibson, surgeon to the departments of the eye, ear, and throat, Brisbane Hospital. Neurology and Psychiatry: Dr. F. Truby King, superintendent of the Hospital for Insane, Dunedin. Diseases of Children: Dr. A. Jefferis Turner, physician to the Hospital for Children, Brisbane. Naval and Military Surgery and Medicine: Surgeon-General W. D. C. Williams, Director-General of the Army Medical Services of the Commonwealth. Skin Diseases, &c.: Dr. W. McMurray, dermatologist to the Sydney Hospital. The subjects selected for discussion in special meetings of the whole Congress are: (1) the relations of the medical profession to hospitals and (2) syphilis. The sectional committees have also selected subjects for discussion in the different sections and are in communication with leading authorities in the different States in securing reports, papers, and exhibits.

Hospital Affairs.

The subcommittee of the Melbourne Hospital appointed to consider the question of rebuilding on another site has presented a progress report. Several suggested sites had been inspected and the most suitable was the ground used as a horse and pig market. The Premier had promised to try to arrange an exchange of sites, so that the city council could give up the market site, and also to purchase for the Government the present hospital grounds at a fair valuation—probably about £100,000.—At a meeting of the committee of the Melbourne Hospital on June 11th a recommendation from the medical staff for the appointment of registrars was considered. It is a remarkable circumstance that though the staff made similar recommendations many years ago, and from time to time since, and although the committee has framed rules for the duties of the registrars, nothing further has ever been done, and now the president, while approving of the suggestion, said that it would not be advisable to make the appointments for some time. Owing to the way in which the records of cases are kept at the hospital it is impossible to get any trustworthy information or statistics from the case books.—On June 4th a meeting of about 70 subscribers to, and former patients at, the Victoria Sanatorium for Consumptives at Macedon was held to consider complaints which had been made concerning the management of the institution. These complaints were explained by Mr. Duncan Turner who had been connected with the institution for many years but who had lately been away in another State and on his return had found that affairs were not satisfactory. The institution was supposed to be a charity but he stated that patients were not admitted to it unless they paid. The secretary practically said that "there is no room for anyone who comes without money but if you pay you can get in at once." Patients complained of the management of the place and gave instances of extravagance. Mr. Turner had written to the committee last January asking for an inquiry but the committee had refused, and as he was again about to leave the State he had taken steps to get this meeting of subscribers called. A letter was read from the secretary explaining that when Mr. Turner wrote in January the committee asked "for specific instances of mismanagement and against whom directed" and asked for a conference with the signatories to the requisition for a meeting, but its requests were ignored. A resolution was passed that the meeting, "having heard the opinion of Mr. Turner and others that the management of the sanatorium is not at all

the academic procession to the service at the Cathedral and the various social gatherings have attracted a good many well-dressed spectators. The tradesmen appear to have dressed their windows in some instances with an obvious appeal to the professional knowledge of the visitors. In the vegetable market there was one amusing example of this, for there were placards announcing under the head of "medical advice" that the banana, according to Professor Metchnikoff, was the fruit above all fruits which was free from bacteria owing to the protection afforded by the thick skin! It was gratifying to find that the "medical advice" was no worse than this.

On Monday afternoon the reception of the Association by the civic authorities took place in the Guildhall. The Mayor (Alderman W. H. Reed) was accompanied by the Sheriff (Dr. B Pickard). On the bench with the Mayor and the Sheriff were Dr. R. A. Reeve of Toronto, President of the Association; Dr. H. Davy, the President-Elect; and many of the officers of the Association and chairmen of branches. Mr. E. J. Domville, the Vice-President of the South-Western branch of the Association, introduced the President, the President-Elect, the chairman of the representative meetings, Dr. J. A. Macdonald of Taunton, and Dr. P. M. Deas, President of the South-Western branch. The Mayor, in response, welcomed the Association and wished the meeting every success.

On Monday evening Dr. Davy entertained a number of guests at the New London Hotel. Among those present were Lord Fortescue, the Bishop of Exeter, the Bishop of Crediton, Sir John Kennaway, M.P., the Mayor of Exeter, Professor W. Osler, Dr. J. W. Tatham, Dr. W. Hale White, Mr. H. T. Butlin, Sir Victor Horsley, Sir John Moore, Dr. Dawson Williams, and Dr. H. P. Cholmeley. After dinner Dr. Davy's guests adjourned to his residence, Southernhay House, where Miss Davy was "At Home." The beautiful garden was illuminated and music was supplied by the string band of the Royal Marines. A large number of guests attended and as the rain held off a most enjoyable evening was spent.

The annual exhibition of drugs, special foods, and surgical and hygienic appliances was held in the Victoria Hall, Queen-street. The building, which is designed for the holding of concerts, lectures, social gatherings, and so forth, afforded a somewhat welcome change from the rendezvous of previous years, which has usually been "the drill hall." "Drill halls" are not, as a rule, designed with any regard to the æsthetic sense; they are constructed merely from the point of view of economic accommodation. The Victoria Hall contains at one end an organ and orchestral staging and at the other end a platform under a dome. The orchestral staging was levelled by a temporary structure, and here were to be found beef extracts, a stuffed ox, surgical appliances, and so on, grouped in front of the organ pipes. The platform under the dome was given up entirely to a very fine exhibition of aseptic appliances, hospital furniture, and surgical instruments.

Even early on the opening morning (Tuesday) the exhibition was the scene of a busy gathering of medical men intent on discussing the merits of the various exhibits. The interest seemed to centre most round the exhibits of surgical instruments and of the apparatus designed for the improved application of the x rays for diagnostic purposes. A pleasing feature of the exhibition this year was that many of the exhibits were of a really scientific character. This applied particularly to x ray apparatus and to some very fine crystalline specimens of synthetic drugs and to microscopic objects. The attendance at the exhibition was more than usually good and the constant stream of well-known representatives of the medical profession through the passage ways intersecting the exhibits must have been gratifying to the exhibitors. In another column we commence a detailed notice of the more important exhibits classified, as in previous years, under the following heads: (1) Surgical Instruments and Appliances; (2) Drugs; (3) Foods and Food Products; (4) Sanitary Appliances; (5) Mineral Waters, Beverages, &c.; (6) Publications; and (7) Exhibits of a Miscellaneous Character. On the whole, Divisions 1 and 2 presented a more imposing array of exhibits than did the others.

The sanitary authorities at Exeter were able to invite visitors to inspect two interesting departures in regard to water-supply and the disposal of sewage. The city may claim to have been the first to adopt a system of sewage disposal depending upon the peptonising and nitrifying action of bacteria. The first septic tank on any sort of a practical scale was installed at Exeter and its success was the means of inducing other authorities to adopt the same principle of disposal. A noteworthy feature of the water-supply is that a new and original design of sand-washing apparatus has been installed at the works, which are situated up the beautiful valley of the Exe about two miles above the city. The filter-beds, turbine pumping engines, and other accessories of well-planned modern waterworks were viewed with interest by those particularly concerned in such questions.

The adjourned general meeting (adjourned from Saturday, July 27th) was held in the theatre at 2.30 P.M. on Tuesday, the 30th. The retiring President, Dr. Reeve, in a short speech reviewed the events of the year of his presidency, after which Dr. Davy, the President for 1907–08, took the chair and returned thanks for his election. Mr. G. O. Franklin then moved a vote of thanks to the retiring President in the following terms:—

> That the warmest thanks of the Association be given to Dr. Richard Andrews Reeve for so ably presiding over the Association during the past 12 months, and that in accordance with By-law 36 he be, and he is hereby elected a vice-president of the Association for life.

This was carried by acclamation and Dr. Reeve returned thanks. It was then decided to accept the invitation of Sheffield for the meeting of 1908 and Mr. Simeon Snell was announced to the meeting as the President-elect for next year.

Dr. Deas, the President of the South-Western Branch, then rose and announced that the branch had decided to present to Dr. Davy, Mr. Russell Coombe, and Dr. William Gordon a copy of the work, "A Book of the South-West," which had been prepared in memory of the visit of the Association in place of the usual local guide-book. The book in question is one the object of which is to "provide a reliable work of reference for those who may be called upon to recommend a locality in Devonshire or Cornwall, either for a short stay or for a permanent residence." It contains a chapter on climatology, a historical chapter, a chapter on the "Secret of Cornwall" by Mr. A. Quiller-Couch, and various other interesting information. There are many illustrations, some of the most notable being those of the beautiful chancel screens which are such a feature of the West of England and the sister district of Brittany.

The usual special service in connexion with the meeting was held in the Cathedral Church of St. Peter at noon on Tuesday, July 30th. Many members of the Association attended in academical or other robes. These assembled in the Chapter House, where they awaited the Bishop, the other clergy, and the choir. A procession was then formed, the choir headed by the processional cross leading, followed flexed upon the trunk; in other words, it should remain in its natural relation to the body, otherwise respiratory difficulties may be considerable. Provided, however, that the airway be kept absolutely free respiration will generally proceed quite satisfactorily.

Patients with any pre-existing respiratory affection should not, as a rule, be placed in the Trendelenburg posture and should it be found impossible to avoid cyanosis in this posture it should certainly not be maintained for any prolonged period. It is also questionable whether etherisation by means of a "close" inhaler should be maintained for any considerable time in the Trendelenburg posture.

A Case of "Early Syncope" under the A.C.E. Mixture, with Remarks.

Any observations likely to throw light upon the etiology of so-called early syncope are to be welcomed by all who are interested in the clinical aspects of general anæsthesia, and I therefore venture to publish the following case which occurred in the practice of a highly qualified medical man who has had a large experience in administering anæsthetics.

The patient was a female child, aged four years, healthy, bright, and well nourished in appearance, and free from all nervousness or fear. As subsequent events proved she had slight "adenoids." No visceral abnormalities were detected. General anæsthesia was required for opening a small superficial abscess of the neck. The following are the notes of the administrator:—

I started with chloroform and used a towel pinned up into an inhaler. The chloroform was continued for between two and three minutes. I noticed that the breathing was rather light, but it improved when I started the A.C.E. This was given for about two minutes and immediately after the head was raised she retched and turned rather pale, and at the same time, or perhaps a little afterwards, the breathing became more shallow. Within half a minute the breathing ceased and I could not feel her pulse. The legs were raised and I pulled her tongue forward rhythmically. Within 20 or 30 seconds she recommenced to breathe, whilst the colour still remained bad and no pulse could be felt. She did not at first breathe automatically but only each time the tongue was pulled forward. Her lips were rubbed and she had liq strych. m. ½ hypodermically. The pulse was perceptible in, I should say, about one and a half minutes after the cessation of breathing.

The operation was not performed. There was a good deal of vomiting, with some prostration during the 24 hours after the administration. A week or two later I was asked to anæsthetise this patient, and having been furnished with details of what had occurred I proceeded as follows:—

Chloroform was dropped upon a Skinner's mask whilst the child counted up to 30. The C.E. mixture was then substituted. In from two to three minutes from the commencement the child was pale, the breathing shallow, the pulse small but palpable, and the corneal reflex present. An ether inhaler was now applied and the pulse and breathing immediately improved. In two minutes the operation was begun. There was no reflex movement. Ether was continued for two or three minutes when the operation terminated. The fauces were then stimulated by the finger and two or three ounces of stomach mucus were ejected. Some post-nasal adenoid growths were now removed by scraping. There was no further difficulty. Vomiting occurred fairly frequently till next day, but there was no depression such as that which had occurred in association with vomiting after the previous administration.

The first question which presents itself in considering this interesting case is: What was the nature of the peculiar state of respiratory and circulatory depression into which this patient passed on both occasions whilst inhaling a chloroform and ether mixture, and before true anæsthesia had become established? It is not uncommon to meet with symptoms of this kind, particularly in children, during chloroformisation. Whatever the condition may be, it seems to be one in which, for some reason or another, the arterial system is comparatively empty; and from the fact that raising the feet and lowering the head prevents, or successfully remedies, the pallor and pulse feebleness, it is probable that the distribution of blood is very similar to that which obtains in circulatory shock; in other words, that the venous system and particularly the splanchnic area is comparatively full. Have we here some peculiar vaso-motor effect causing an early and abnormal fall in blood pressure? Or is the state one of reflex cardiac inhibition, brought about by the impact of the anæsthetic vapour upon the sensory nerve endings of the respiratory tract? There is good evidence that chloroform vapour may thus produce cardio-inhibitory effects; but the researches of Embley and others indicate that inhibition of this sort is rarely, if ever, dangerous to life. Is the condition in some way connected with the act of vomiting? It is certain that when food or swallowed mucus is present in the stomach chloroform often produces eccentric phenomena such as those under consideration, and that such phenomena vanish when vomiting has taken place. I fear that our knowledge is at present insufficient to enable us to state positively what is the nature of these early manifestations. It is interesting that they do not occur under nitrous oxide or under ether. It is also interesting that they may be made to vanish in more ways than one, as I shall presently explain. But what the precise nature of the phenomena may be I fear we are not in a position to define.

The second question before us is: *What treatment should be adopted?* This question is comparatively easy to answer. There is little doubt, I think, that the application of an ether inhaler is indicated when such symptoms arise. I have never known this treatment fail to restore the colour, pulse, and respiration. Opening the mouth, stimulating the fauces, and inducing retching will also answer well, for the straining movements thus induced tend to empty the veins and particularly the splanchnic vessels, and thus to fill the arterial system. As already mentioned, partial or complete inversion will also prove successful. Of all these measures, however, a change from chloroform to ether gives the best results and the ether seems to answer most satisfactorily when administered by means of a "close" inhaler.

The third question to be considered is: Does this peculiar state of depression ever terminate fatally, and if so, in what way does the fatal issue come about? It is in the highest degree probable that this early syncopal state is not of itself dangerous, but that unless properly treated it may readily become so. If, for the sake of argument, we admit that the condition is principally referable to cardiac inhibition there is little or no likelihood of this inhibition proving fatal *per se* so long as the anæsthesia is but light, for it is necessary, as Embley has shown, for the heart to be itself damaged by deep anæsthesia for the inhibitory effect to prove dangerous. Nor is there any definite evidence that the circulatory disturbance incidental to vomiting is dangerous *per se*. The condition, whatever its nature may be, is probably only likely to threaten life if some other condition—e.g., slight asphyxia from one of the many causes capable of inducing asphyxia—be superadded to the syncopal state. In the case under consideration it is quite possible that the act of retching, coming about as it did during circulatory depression, rendered that depression acute by adding to it a slight asphyxial factor. I have certainly seen several cases which tend to support this explanation. At the same time one must not be too positive of its correctness.

A Case of Intercurrent Asphyxia during the Anæsthetisation of a Patient in whom Excision of the Tongue had been Performed.

The following case, which is unique in my experience, occurred in my practice a few months ago, and although it may never perhaps fall to your lot to administer an anæsthetic under precisely similar circumstances, the case is, I think, worthy of record.

The patient was a man, 43 years of age, of spare build. He was not nervous. There was a history of syphilis. About a year before the administration now to be described he had developed epithelioma of the tongue and cervical glands; and he had recently undergone two operations with an interval of some weeks, one for the removal of the glands and the other for excision of the tongue and floor of the mouth. He made an excellent recovery from both these operations. The epiglottis had not been removed as it was found to be unaffected. Since the excision of the tongue the patient had been troubled by mucus and saliva collecting in the mouth—a common occurrence after such operations. At the time of my administration there was still an unhealed area within the mouth causing some discharge. Three or four roots of teeth were to be removed, and the anæsthetic chosen was nitrous oxide mixed with oxygen.

A prop having been inserted I administered nitrous oxide and oxygen by the usual method, the patient sitting in a chair. The mixed gases were breathed freely. There was no excitement or movement. In from 30 to 40 seconds from the commencement of inhalation a curious inspiratory sound, stridulous (i.e., laryngeal) in type, became audible. It was a sound that I do not remember to have heard before under nitrous oxide or nitrous oxide and oxygen, although it is not uncommon under other anæsthetics. It was not a loud sound; in fact, I should probably not have heard it had the room been noisy. It lasted for from five to ten seconds, at the end of which time respiration abruptly ceased. The colour and pulse being good, and thinking that the arrest of breathing would be but temporary, I did not remove the face-piece. Two or three seconds later, however, the breathing still being in abeyance, I thought it best to withdraw the anæsthetic and allow the operation to begin. Temporary suspension of breathing is not uncommon under nitrous oxide or nitrous oxide and oxygen and is generally dependent upon deglutition movements. There had been no asphyxial phenomena up to this point—no stertor, lividity, jactitation, or separation of the eyelids. The commencement of the operation did not, as it sometimes does, re-establish breathing, nor did it cause any reflex movement. So great was my confidence in the safety of the anæsthetic that I permitted of a tumour, for life could be thus prolonged and distressing symptoms relieved. He emphasised the importance of this procedure as a means of arresting optic neuritis and of saving sight, though it must not be supposed that every patient suffering from optic neuritis had an intracranial tumour, or that optic neuritis of toxic origin would be relieved by trephining. In conclusion, he referred to the circumstances under which lumbar puncture could be substituted for trephining. It should, however, be regarded only as a palliative measure which could not be expected to relieve the symptoms permanently. It was valuable as a means of relieving urgent symptoms of pressure, when to wait for a surgeon to trephine would be to allow the patient to die, or when the patient's condition was too bad to permit of the major operation. He considered that it was a procedure which should be employed for diagnostic purposes and for the relief of urgent symptoms in cases of intracranial tumour, but which should not be regarded as likely permanently to relieve symptoms, to prolong life, or to effect a cure. In quoting cases in illustration of his remarks he referred to a typical example in which the diagnosis of cerebral tumour was easy and the operation successful; to another in which, although the operation was successful, the diagnosis was less accurate, in that an intramedullary cyst of the cerebellum was discovered instead of a tumour external to the organ; to a third, in which the diagnosis of tumour seemed certain, and yet this was not discovered at operation, although the patient subsequently recovered from the symptoms that suggested the diagnosis which led to the operation—cases of this kind were referred to in Germany as "pseudo tumours; to a fourth, which showed how cerebral thrombosis might be readily mistaken for tumour; and to a fifth, in which disseminated sclerosis accounted for the clinical picture, although the earlier symptoms strongly suggested a tumour of the mid-brain.

Sir WILLIAM MACEWEN (Glasgow) referred to the fact that he had found it unsafe to trust to the classical symptoms of intracranial tumour in diagnosis and mentioned a case in which early in his work on intracranial surgery he had refused to operate, which subsequently proved to be of this nature. He now looked carefully at other symptoms, including the state of the mental condition, in order to assist him in arriving at a diagnosis. He was glad to hear what Dr. Risien Russell had said in connexion with the removal of syphilitic growths. Early in his work he had been criticised for operating in such a case, but he held that where caseation had occurred and where the gumma was large no amount of potassium iodide and of mercury would remove it, and even if they could do so it would require a very long time. He therefore operated early after anti-syphilitic treatment had received a sufficient trial. With reference to the carrying out of operation in two stages, the custom in Scotland was to complete the operation at once if the condition of the patient permitted this to be done, but otherwise to carry it out in two stages. In regard to the results of operation, he never told the patient definitely what the result would be, for while sometimes permanent paralysis results he had been greatly impressed by the fact that sometimes when he expected to find definite and permanent paralysis afterwards it had completely cleared up. In regard to the choice of cases for operation, if he were definitely of opinion that permanent hemiplegia would necessarily follow he would hesitate to advise operation, as also if aphasia were certain to follow. Referring to lumbar puncture, except for purposes of diagnosis and for giving temporary relief to pressure symptoms he did not think there were yet sufficient data to determine its value as a means of treatment.

Dr. J MICHELL CLARKE (Bristol) referred to the difficulty in diagnosis in those cases mentioned by Dr. Risien Russell, to which the name of "pseudo-tumour" had been applied in Germany, in which the symptoms were those of cerebral tumour but in which no tumour could be found, and gave an account of the common clinical features in a certain type of these. Nonne had reported 11 cases of this kind. As a rule, the patients were women and generally young. Cerebral tumours may first come under observation when hæmorrhage occurs into them and thus give rise to difficulty in diagnosis. The difficulty in localisation was also increased by not knowing the size of the tumour. There was also great difficulty in connexion with growths in the temporo-sphenoidal region. He alluded to cases of tumour of the cerebellum and mentioned cases he had seen. There was especial difficulty when the tumour began by causing auditory symptoms, such as those of Ménière's disease. Since the auditory symptoms precede the actual symptoms of tumour by a long period these were often due to neurofibroma of the auditory nerve and were favourable for operation. He discussed the significance of local tenderness, the alteration of the percussion note over the skull, and the occasional help afforded by alterations in the shape of the skull which might only be brought to light on shaving it. Treatment of intracranial tumour practically resolved itself into operation. In regard to syphilitic cases, he recommended that if three to four weeks' treatment by potassium iodide and mercury failed to give definite relief it was useless to persist and operation should be performed. He supported the views expressed as to the great value of palliative trephining. In connexion with the question as to operation in one or two stages, he advised that, where possible, an estimation of blood pressure should be carried out during the operation and where this was well maintained that the operation should be completed in one stage.

Mr. R. MARCUS GUNN (London) would only discuss the matter of operation in regard to its effect upon vision and the indications for operation. He described the manner in which the optic nerve comes to be affected in cerebral tumour. It was a clinical observation of great importance that optic neuritis was compatible with perfect vision as shown by Dr. Hughlings Jackson. It was also definitely established that optic neuritis may occur and leave no opathalmoscopic sign. Although optic neuritis or papillitis was so called actual evidence of its inflammatory nature was wanting. Mr. Gunn held the view that the changes observed are an evidence of œdema and that the excess of fluid within the intersheath space surrounding the nerve acts mechanically. He reminded his audience of the anatomical relations of the optic nerve and brought forward evidence supporting his views. Various clinical stages might be recognised in the course of optic neuritis or "tumour papillitis," and he proceeded to describe five of these. In the first stage there was redress of the disc with loss of definition in its edges, slight prominence of its surface, and narrowing of the physiological pit. In the second stage there was increased swelling of the papilla with disappearance of the physiological pit. The retinal vessels at this stage showed signs of retarded circulation. In the third stage the papilla gave evidence of further swelling and the venous distension was very marked. Fine folds appeared in the œdematous retina and retinal hæmorrhages might occur. In the fourth stage the papilla was more opaque and sometimes more prominent, the hæmorrhages increased in size and number; vision might become impaired at this stage. In the fifth there was decreasing vascularity of the papilla and parts of its surface became paler, the prominence persisted or slowly subsided. In regard to the first three stages the prognosis was good as regards vision after operation; it was bad in the fourth, and in the fifth it was useless to undertake operation with a view to improve vision. In connexion with the results of operation Mr. Gunn had found that the degree of swelling of the papilla afforded no indication of the visual prognosis; that retinal hæmorrhage was no contra-indication; that subsidence of the swelling of the disc is first apparent some days after the opening of the dura mater; that the effect on the papillitis is not earlier or better when the tumour is removed than when the dura mater is freely opened, and that the improvement after operation may ultimately be very satisfactory, although long delayed. Some of the most striking results of operation as regards vision were seen after operation for cerebellar tumour. Comparing the various methods of relieving tension he referred to lumbar puncture, but said there was as yet insufficient experience as to its value but it would probably need to be repeated frequently. Opening the optic nerve sheaths behind the globe was difficult and less successful than trephining the skull.

Dr. G. NEWTON PITT (London) would like to know in what proportion of the cases of cerebral tumour operation was possible and its results satisfactory. He drew attention to the difficulty in diagnosis occasioned by internal hydrocephalus following accident. He quoted a case of cerebral tumour in which repeated drainage of the lateral ventricles gave relief. He inquired whether the cases of so-called "pseudo tumour" might possibly be due to obsolescent tubercle.

Mr. DONALD J. ARMOUR (London) was of opinion that the as it is in the mouse. Nevertheless, these results obtained in the mouse are *so excellent that they must encourage us* energetically to pursue the path of these discoveries.

I had mentioned in my last lecture that it is possible to obtain strains of trypanosomes which are resistant to these active substances. These studies, which I carried out together with Dr. Röhl and Dr. Browning, have shown this *resistance to be of a very high degree.* Thus atoxyl-fast strains show no sign of being influenced *by the highest doses* applicable to mice. I gave you the explanation for this resistance—viz., that it is the result of a decrease in the avidity of the trypanosomes for the substances in question. Further, I showed you that, apart from this resistance, the parasites' protoplasm, though not their nuclei, had become hypersensitive towards *the arsenical preparation. Thus* we here meet with an important instance of association in one and the same cell of resistance and hypersensitivity. This association, which is of late years proving to be of increasing importance in the question of mammalian immunity, is therefore present even in so simple an organism as that of the protozoon.

Although in the mouse atoxyl-resistance usually occurs only after a fairly long interval I have occasionally seen it already after a fortnight. This observation is very important, because it makes it possible that the negative results observed by Ayres, Kopke, Broden, and Rodein van Campenhouh *in cases of sleeping* sickness that had received a long-continued treatment may also be due to such a resistance.

As against atoxyl, trypanosomes can also be rendered resistant against parafuchsin, trypan-red, and trypan-blue. Further, it was shown in my institute by Franke that it is even *possible for trypanosomes to* become resistant against those protective substances which are formed after the recovery of the host from a trypanosomic infection. A similar discovery has recently been made by Levaditi in the spirochætæ of relapsing fever. This is therefore a general law, and it is especially important because this change in the trypanosomes, having *once become acquired,* remains a hereditary property. Thus I have cultivated for 125 generations my atoxyl-fast race, without finding any decrease in its powers of resistance. We must, further, note that every such resistance is specific. Thus the fuchsin-fast races are resistant only towards *this* body, but not towards atoxyl and trypan-red, and *vice versâ.* This resistance extends, however, to chemically different substances of the same group, so that we can in any individual case decide to which group a given new trypanocidal remedy belongs. Thus, for example, the atoxyl-fast race is resistant also against a number of *related substances. From among* any hundred trypanocidal bodies it is thus possible to single out those substances which contain arsenic.

It has further been shown that the resistance against trypan-red and trypan-blue is a mutual one in spite of the considerable chemical differences between these two substances, *which, in fact,* have nothing *in common* with one another except that they contain naphthalin rings which are substituted in a certain position (3, 6) by sulphuric acid radicles.

Thus we possess in the specific resistance, so to speak, a therapeutic sieve, a "*cribrum therapeuticum*" with which we can *undertake the classification of* any new remedy *of* this kind. If such a remedy is found to destroy all three of our resistant races it needs must belong to a fourth group. One can, of course, materially simplify this examination by employing races that have *been rendered resistant against* all the *groups hitherto* known. Thus I have, together with Dr. Browning, obtained such a race which is resistant against atoxyl, trypan-red, and fuchsin. By using such a race, a single animal experiment suffices for the purpose of establishing any new group of *remedies. For,* if one injects the substance in *question to* such a trebly resistant mouse the trypanosomes will either go on proliferating—then the substance must belong to one of the three known groups—or the trypanosomes are injured; in that case we have before us a new type. As you see, we are therefore *enabled* by means of these resistant races to separate substances of different mode of *action* from one another and thus to solve a problem which hitherto could not even be asked. A way is thus shown us, by which we may enter into the finest mechanism of pharmaco-dynamics and, if I may *say so, obtain* a fuller knowledge "de sedibus *et causis* pharmacorum."

On this occasion I wish to lay special stress upon my view that the medicaments are also attracted to, and bound by, certain atom groupings of the protoplasm molecule. I am inclined to look upon this as somewhat analogous to the binding of the toxins and of similar proteid bodies. Yet, on the *other hand, there* are *fundamental* differences between the two. For, as I have always *insisted* in my former publications, the mode of binding the toxins is peculiar in so far as it is the result of a certain kind of assimilation which obviously consists in processes of a more or less *synthetic* nature. These toxin-receptors which produce immunity are *bodies of* a more independent character, and appear to be especially destined *for the purpose of* assimilation. This high degree of independence is evidenced by the fact that, in conformity with my side-chain theory, these receptors are very easily reproduced by the cell in excessive number and after being separated from it find their way into the blood.

I have now come to hold the opinion that *also* a *part of* the chemically defined substances is attached to the cell by groups corresponding to these receptors; these atom groupings I will distinguish from the toxin receptors by the name of "chemio-receptors." *This* view is more especially supported by the *fact* that, *as I stated before, the* atoxyl-fast race is also resistant against a number of substances related to atoxyl, but otherwise showing widely different chemical characteristics. Evidently, therefore, it is here the arsenic acid radicle which represents the point of *attack common to this series of substances. It is the arsenical radicle* as such which is bound by the *chemio-receptors. These chemio*-receptors must, however, be regarded as of a simpler structure than the toxin receptors. They do not show a similar degree of independence; they cannot, therefore, become increased in chronic intoxications, and since they are sessile *cannot be thrown off into the blood. The number of such* chemio-receptors which a trypanosomic cell possesses for poisons represents the number of points of attack. By means of the resistant races we can count off one by one these groups that are open to attack.

The discovery of any trypanocidal *substance* will always be the *result of chance and trial. Every* point of attack may, of course, be liable to attack by a host of different bodies, all of which have one specific group in common. It must be the goal of our experiments to seek out, by systematic chemical researches, *the most suitable substances* and thus *to discover the "optimum centres."* This problem is by no means an easy one, since, according to my experience of many years, which agrees entirely with that of Mesnil, different animal species have different such optima, and since, therefore, the work must be specially done for each species of animal and each *kind* of trypanosome. Thus, for example, in the mouse, Trypanosoma Gambiense is far more easily attacked by arsenical preparations than the other races of animal pathogenic trypanosomes, whilst fuchsin and its relatives show an exactly opposite action. Still, after *all,* this problem is *not* insoluble, since there is *only* a limited *number of animal species and of* trypanosomes; we may, therefore, cherish the hope that the united forces of the men who are at work on this subject in various laboratories will succeed in attaining that practically most important end, the victory over sleeping sickness.

Especially with a view *to practical* therapeutics the knowledge of the different points of attack is important, since it furnishes us with the possibility of fighting the disease by combined several remedies. The principle of *this* combinatory method of therapeutics is to attack *the* enemy *simultaneously from two or three* sides, and thus to produce a completely successful result by combining several different substances, each of which alone does not show a sufficient effect. Thus it has been found by Laveran and by Franke that certain infections which are influenced *neither* by *trypan-red nor* by atoxyl *alone* can be cured if these two substances are used in combination. I, too, have in course of time repeatedly met with similar cases *and* am convinced that substances which by themselves are not very *efficient* may yet produce good results if they are used as supplements *to more powerful,* though *not* completely curative, bodies. Supposing, for example, a highly trypanocidal remedy to kill 98 among 100 parasites, its administration would be *followed by* an instantaneous improvement but *not* a definite cure, since the two surviving trypanosomes *must* in course of time produce a relapse. But if one combines this powerful remedy with another one which, even though much weaker, *yet suffices to* kill just those two surviving but already weakened parasites, then such a combination would serve *to* bring about an otherwise unattainable *cure.* In this respec later and more severe stages by earlier diagnosis and more complete and efficient treatment of the disease as soon as it is recognised. Statistics reveal the fact that of the total mortality more than half arises from forms of disease which are capable of prevention and which with early diagnosis and efficient treatment might be so far palliated or prevented as to remove the loss of time and consequent loss of value to the community arising from the death or invalidity of the person attacked. Further than this, as knowledge increases and improved methods of dealing with all classes of disease come into action, it will shortly be necessary to increase largely the number of diseases which can be classified under the heading of preventable disease. For example, the whole class of diseases arising from syphilis are still being far too much neglected when the effects upon the coming generation are considered. Hitherto the self-denying efforts of the medical profession have been mainly in direction of personal hygiene while the community at large has been forced to accept in great part a responsibility for the prevention and treatment of some of the more important epidemic diseases. The relationship which is so constantly asserted to exist between poverty and disease must be looked at from both sides, and disease is by far the more important as a cause of poverty than is poverty of disease. Disease may be due to poor surroundings but is rarely due to privation and (except in young children) to lack of sufficient food. Therefore it may be possible to prevent people from becoming poor by keeping them free from disease. What is being done officially? I may refer to the action of municipal and local sanitary authorities in the utilisation of the services of the medical officer of health for diagnosis and for precautionary measures against further outbreaks, coupled with the provision of home treatment and the distribution of antitoxin and the employment of municipal nurses. The extension of all these measures to the prevention and mitigation of pulmonary tuberculosis and the provision of gratuitous bacteriological verification; the supervision of midwives, and in one town even the financing of an ordinary general hospital from part of this municipal work. Boards of guardians are in charge of vaccination and of the gratuitous administration of medical relief which is better in theory than it has proved in practice; the administration and use of Poor-law infirmaries as adjuncts to the general infirmary by the admission of cases unsuited to the latter are also part of their functions. School authorities are also awaking to certain needs; the regular inspection of children (shortly to be made compulsory) and the need for systematic examination of bodily defects have been seen to be matters of grave importance, and the school doctor must be followed by the school nurse, and examination by some measure of treatment. There are also minor details, such as the establishment of municipal milk depôts and the free distribution of diarrhœa mixtures. It must be remembered that all these things except Poor-law medical relief are carried out irrespectively of the test of poverty. Thus it will be seen that it is impossible, logically or practically, to separate prevention and treatment, and this will become increasingly true as measures for prevention are efficiently carried out. The supervision of preventive measures generally necessarily involves more or less treatment. Thus it is not surprising that medical men complain of the decay of private practice; the number of deaths occurring in institutions has risen in 30 years from 8·3 to 16·2 for the whole of England and Wales, and for London alone from 16 3 to 34·9; these figures are eloquent in their lesson. One person in every six dying in the country dies in an institution, and in London the proportion is double—viz., 1 in 3. But even with this vast array of public medical services the waste, overlapping, and inefficiency of the whole thing must be at once obvious. The present condition of things is equally unsatisfactory to both doctor and patient; the former considers that he is underpaid and the latter, while he may not think much about the fee, feels that he is not getting from his club doctor what he can get elsewhere at a cheaper rate and often in a better form. And so for want of a system and of coördination the whole service fails of its proper ends in many ways. In the first place, there is little chance of early diagnosis and the resulting dangers are obvious. Next, a delay in diagnosis is followed by a curtailed treatment, and much of this is given under conditions of loss of time which involves a serious loss to the community. Coördination is entirely lacking and vast quantities of valuable material are lost and wasted for want of a proper central organisation. This applies not only to the conditions of disease but to those which induce disease and thus prevention is gravely hindered. Coördination may be exemplified by the methods in vogue at Brighton for dealing with tuberculosis, while no better example of incoördination can be adduced than the present chaotic methods of school examination in which there is a complete lack of intelligent coöperation between the various workers. The present condition of the medical services must be considered to be transitional, and as it seems impossible to arrest the steady trend of all communities to treat an increasing amount of general disease at the expense of the community under either compulsory or voluntary systems it is better that the problem of coördination should be faced and that some attempt should be made at least to get value for money in the performance of the work—a thing which no one gets at present. The economic aspects of the problem are, of course, serious and far-reaching; the question of pauperising the people may be dismissed after the experience of free education; in fact, such a system is more likely to increase self-help. Such a public medical service must centre round the present sanitary departments; it must embrace every form of disease and every means of maintaining health, and thus information which is of the highest importance to public health must no longer be run into culs-de-sac and wasted but must be utilised to the full extent for the public welfare.

Dr. H. COOPER PATTIN (medical officer of health of Norwich) congratulated Dr. Newsholme on his paper. He desired particularly to emphasise the analogy of free education to a free medical service. The present evil was that the key to the provision of free medical service was destitution, which was a mistake. The public required sooner or later the reorganisation of the public medical services and this must take the form of a coördinated medical service centred on the present sanitary authority. This might be hoped to result in the elimination in time of the most dangerous factor in the present production of disease, namely, delay. Disease must be sought out and prevented and we must not wait for it to cry aloud for assistance. There was also a grave need for the provision of regular instruction in hygiene in elementary schools so that the coming generation might learn to coöperate with the profession and the community in the prevention of disease.

Mr. R. DENISON PEDLEY (London) laid especial stress upon the great importance to the community of coöperation between the health department and the dentist. Infantile mortality is one of the greatest problems of the day and is largely due to improper feeding; the same cause is also largely responsible for the production of inferior dental tissue. The delay spoken of by Dr. Pattin was amply illustrated by cases attending a dental out-patient department. The mothers among the poorer classes are hopelessly ignorant upon the question of proper food.

Mr. T. GARRETT HORDER (Cardiff) spoke most strongly on the need for coördination but also emphasised the need for home visiting and home teaching. In this scheme of coördination the public vaccinator must find a place as an integral part of the work of preventive medicine. As a regular visitor to the homes of the poor he had exceptional facilities for acting as a health missioner.

Mr. H. H. TIDSWELL (Torquay) was pleased to find Dr. Newsholme in sympathy with the general practitioner. He thought elementary school children were martyrs who needed the championship of the medical profession. The inspection of children could only be efficient by coördinated work between the school medical officer and the private practitioner who sees the child at home. Too many children were allowed to sit all day in wet clothes and this needed reform.

Dr. WALKER (Edinburgh), as an old collaborator of the President, considered that the future of the national health was bound up with this principle of coördination. There would inevitably be mutual jealousies to be overcome but these would eventually disappear in the cause of humanity.

Surgeon-General Sir CHARLES M. CUFFE, A.M.S. (London), offered his views as a councillor, a guardian, and a member of an education committee: he felt that by hospital abuse much wrong was being done to the medical profession; the treatment in workhouse infirmaries is valuable and as it fortunately does not disfranchise the receiver there is less

The Effect of Posture on Chest Depth.

The change in the width of the dulness would probably be greater than it is were it not that on recumbency the sternum itself usually falls backward towards the *spine. The decrease thus produced in the antero-posterior diameter of the chest varies considerably; in a rigid chest it may not occur at all; in a very elastic chest it may exceed an inch; in Table I.* the average decrease amounted to nearly five-eighths of an inch. The measurements there recorded were made with a specially designed pair of callipers (*Fig.* 2) having one arm capable of slipping under a recumbent patient, the other arched to meet the front of the chest wall, and fitted with a hinge which could be fixed when the instrument had been adjusted before removing it for measurement. The measurements were taken at the nipple level. This change of chest depth, consequent on change of posture, is important because it helps to account for some of the coincident changes in the cardiac physical signs. (The changes in the cardiac sounds will be better dealt with when the changes in cardiac murmurs are presently under consideration.)

FIG. 2.

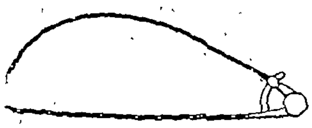

FIG. 3.

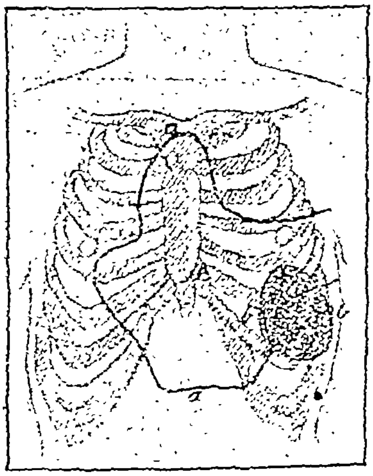
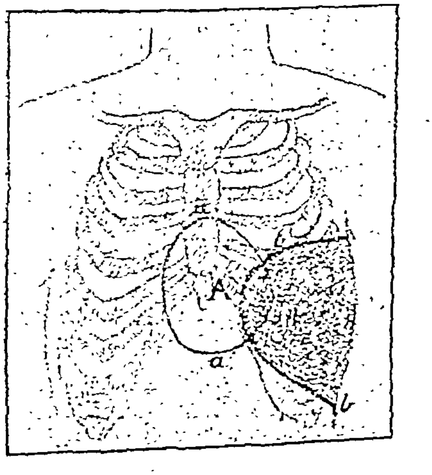


Recumbent position.

FIG. 3 A.



Erect position.

From a case of mitral stenosis. The outline *a a* = systolic murmur area. A = its point of maximum loudness. The shaded area *b b* = presystolic murmur area. + = position of apex beat.

The Effect of Posture on the Heart Dulness in Disease.

The changes which accompany change of position in the cardiac physical signs in disease are often even more striking than those occurring in normal conditions. When the weight of the heart is increased, its fall in the chest, when the erect position is assumed, is sometimes made evident by the descent of the apex beat into a lower intercostal space as in *Fig.* 3, whilst the widening of its dulness is often very remarkable (Fig. 4). I have referred in a former paper[3] to a case of enlarged heart with mitral and aortic disease where the width of dulness was five inches in the recumbent position and increased to eight inches on assuming the erect position. This might be thought to have been an extreme instance, but Table II. shows that it was not so. This table gives the records of 11 unselected cases of enlarged hearts, in one of which the measurements were recorded before and after treatment. The dulness measured was in all cases the relative dulness. The importance of this relative dulness is sometimes under-estimated. *It is, for clinical purposes, the* important heart dulness (although, like other clinical signs, it should not be considered by itself), for the absolute cardiac dulness merely indicates the area uncovered by lung; as Dr. S. J. Gee says,[4] the relative dulness

FIG. 4.

[3] The Influence of Posture on the Normal Cardiac Sounds and on the Normal Cardiac Dulness, Transactions of the Royal Medical and Chirurgical Society, vol. lxxxix., 1906.

[4] Auscultation and Percussion, London, 1893, p. 79.

This was seconded by Dr. K. A. GROSSMANN (Liverpool) and was carried.

Mr. F. RICHARDSON CROSS (Bristol) and Dr. J. HINSHELWOOD (Glasgow) thought that the ophthalmic surgeons should take up seriously the question of trephining for the relief of intracranial pressure and for the relief of optic neuritis.

Dr. LANDOLT had found that in Paris there were much fewer cases of ophthalmia neonatorum.

Dr. WILLIAMS (Liverpool) said that in his district the disease was increasing, and this occurred nearly always in cases attended by midwives.

Dr. A. TROTTER (Perth) said that he hardly ever saw a case now.

Mr. SNELL, in reply, said that unfortunately in Sheffield ophthalmia neonatorum was not diminishing.

Dr. H. FISH (Chicago) read a paper on the Relation of Disease of the Nasal Accessory Sinuses to Optic Neuritis. He affirmed that many cases of optic neuritis were due to sinus disease.

Mr. R. PICKARD (Exeter) described a case bearing on this point.

Dr. E. D. BOWER (Gloucester) quite agreed as to the relation of the two diseases.

Dr. REBER (Philadelphia) thought that the nose was much neglected by ophthalmic surgeons and that unilateral optic neuritis was nearly always due to this cause.

Mr. W. J. CHICHELE NOURSE (London) also described some cases.

Dr. A. HILL GRIFFITH (Manchester) asked if the cases were really optic neuritis or retro-ocular neuritis; if the latter, anything cured them. He asked if those cases had a large central scotoma as the retro-ocular cases had.

Dr. FISH, in reply, said that some of his cases were certainly retro-ocular in nature but many were not.

PATHOLOGY.

WEDNESDAY, JULY 31ST.

The section of Pathology was held in the Barnfield Hall, under the presidency of Professor R. MUIR (Glasgow University) who opened the proceeding by calling upon Dr. WILLIAM HUNTER (London) to introduce the subject of Pernicious Anæmia and Allied Conditions. Dr. Hunter, who discussed at length many aspects of pernicious anæmia, was followed by Dr. LOVELL GULLAND (Edinburgh), Dr. C. H. MELLAND (Manchester), Dr. A. G. GULLAN (Liverpool), Professor J. LORRAIN SMITH (Manchester), Dr. R. HUTCHISON (London), Dr. A. E. BOYCOTT (London), Professor A. R. FERGUSON (Cairo), Professor I. WALKER HALL (Bristol), Dr. F. G. BUSHNELL (Brighton), and Dr. F. M. POPE (Leicester).—After a few remarks of a general character from the PRESIDENT, Dr. HUNTER briefly replied and the section turned to the consideration and discussion of a paper by Professor I. WALKER HALL on the Estimation of Fat in the Fæces, of one by Dr. FRANK C. EVE (Hull) on Motile Bodies in Pathological Cerebro-spinal Fluids and their Origin from Red and White Corpuscles, and of a short communication from Professor J. M. BEATTIE (Sheffield) on a Sporozoon in Aural Polypi. The meeting adjourned.

TROPICAL DISEASES.

WEDNESDAY, JULY 31ST.

The President of the Section, Mr. JAMES CANTLIE (London) gave a digest of the additions to our knowledge of tropical diseases made during the last two years—that is, since this section held its previous meeting. Professor W. J. SIMPSON opened a discussion on Antimalarial Sanitation, in which Professor HANS ZIEMANN (Cameroons, West Africa), Major A. H. NOTT, I.M.S., Dr. W. J. PROUT, (Liverpool), Dr. ANDREW BALFOUR (Khartoum), Dr. LOUIS SAMBON (London), Major G. F. BIRDWOOD, I.M.S., Sir PATRICK MANSON, Dr. H. MARCUS FERNANDO (Ceylon), and Lieutenant-Colonel GILES, I.M.S. (retired), took part.

Major LEONARD ROGERS, I.M.S., gave a Lantern Demonstration of Temperature Charts illustrating the curves in various Indian fevers, including malarial fevers, seven-day fever, three-day fever, typhoid fever, and kala-azar.

DISEASES OF CHILDREN.

WEDNESDAY, JULY 31ST.

The Section of Diseases of Children was held at the Young Men's Christian Association under the presidency of Mr. A. H. TUBBY (London).

The proceedings were opened by a short speech in which the PRESIDENT outlined the business before the section and introduced the opener of the discussion, Mr. D'ARCY POWER (London), who then sketched out the chief features of the Diseases and Displacements of the Testicle.

He was followed in some detailed observations by Mr. RUSSELL J. HOWARD (London), Mr. W. E. DIXON (Norwich), and Mr. W. MCADAM ECCLES (London), Dr. G. H. EDINGTON (Glasgow), Mr. J. P. LOCKHART MUMMERY (London), Mr. P. G. Lee (Cork), Mr. E. M. CORNER (London), Mr. W. F. BROOK (Swansea) and the PRESIDENT also contributing to the debate.

Papers were read by Dr. EDINGTON on Some Abnormalities of the Penis, by Mr. H. T. GRAY (London) on Some Cases in which Meckel's Diverticulum was present, by Mr. C. A. R. NITCH (London) on Cases of Pneumococcic Arthritis, and by Mr. MUMMERY on Cases of Prolapsus Recti.—Mr. BROOKS, Mr. S. STEPHENSON (London), Mr. MUMMERY, Mr. CORNER, Mr. LEE, and Dr. E. CAUTLEY (London) joined in the discussion.

ELECTRICITY.

WEDNESDAY, JULY 31ST.

The proceedings were opened by the PRESIDENT, Dr. LEWIS JONES (London), who briefly welcomed those of the members present, and after paying a generous tribute to the work of Professor Stephane Leduc of Nantes in medical electricity called upon the latter to give the opening address, which was on the "Ions in Medicine."

Mr. A. W. RUD (London) then addressed the section on the Use of the Cryptoscope in Operations for Renal Calculi. His plan is to use a special sterilisable form of cryptoscope by which the kidney can be examined by the screen when brought out through the incision. By this means the renal calculi can be removed by the smallest possible opening.

Professor WERTHEIM SALOMONSON (Amsterdam) described the Einthoven galvanometer, which is an instrument of exceeding delicacy and invaluable for the study of muscle currents and other fine and accurate work.

The VICE-PRESIDENT, Dr. J. DELPRATT HARRIS (Exeter), then took the chair, while Dr. LEWIS JONES showed and explained some oscillograph tracings of medical coil currents.

Dr. HUGH WALSHAM (London) and Dr. HALES DALLEY (London) gave a description and demonstration of the use and advantages of the ortho-diagraph for recording the actual size of the heart, &c.

The first morning's proceedings were terminated by the reading of a paper on the Effects of High-Frequency Currents on the Urinary System, by Dr. W. F. SOMERVILLE (Glasgow).

NAVY, ARMY, AND AMBULANCE.

WEDNESDAY, JULY 31ST.

This section met under the presidency of Deputy-Inspector-General J. PORTER, R.N., who in his introductory remarks described the vast and almost revolutionary strides made by the Royal Army Medical Corps in regard to preventive medicine. He remarked that in the medical service of the Royal navy many improvements had been made during the past decade. Fleet-Surgeon A. GASKELL, R.N., read a paper on the treatment of the wounded in naval actions, and he was followed by Lieutenant-Colonel A. M. DAVIES, R.A.M.C., who spoke on preventive measures against enteric fever and on its spread by personal infection, which he defined as direct or semi-direct contagion. The next paper, on the frequency of aneurysms in the Royal Navy, was read by Fleet-Surgeon P. W. BASSETT SMITH, R.N., and the last paper was by Staff-Surgeon G. E. DUNCAN, R.N., on a form of oral *filter* for use in operating-rooms.

THE ANNUAL EXHIBITION.

The Victoria Hall in Queen-street presented quite an animated and picturesque scene from beginning to end. The stalls were tastefully arranged, the stage at one end of the hall and the orchestra with the organ at the other serving to break the monotony of avenue after avenue intersected with an almost geometrical exactness by transverse rows. The organising committee had evidently contrived to separate as far as possible the various classes of exhibits, so that no two adjoining stalls were devoted to the same subject of exhibition. Now the visitor was confronted with a large assortment of surgical instruments, next he was face to face with some special foods, then he was asked the same rule as that of mitral regurgitation but less constantly. I have figured a case in which it seemed little affected by posture, but in that case there was also adherent pericardium.

4. *Aortic regurgitation.*—Posture seems to have little effect on this murmur.

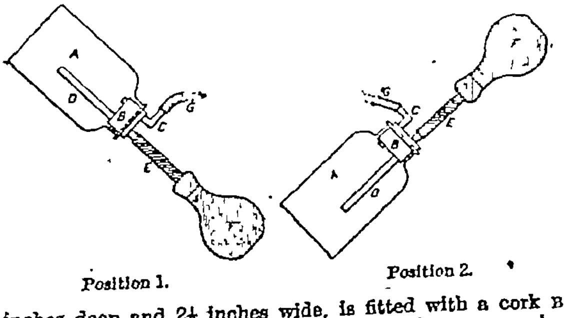
5. *Aortic stenosis.*—This murmur usually follows the same rule as the murmur of mitral regurgitation.

Explanation of the changes in the murmurs.—When looking for an explanation of the changes in the murmurs it occurred to me that, as most of the murmurs are increased on recumbency, perhaps the antero-posterior diameter of the chest might be less in that position. I found it was so. Then it seemed clear that this lessening of chest depth, by bringing the stethoscope relatively much nearer the pulmonary valves, relatively a good deal nearer the aortic valves, and relatively somewhat nearer the tricuspid and mitral valves, should greatly increase a murmur at the pulmonary valves, decidedly increase a murmur at the aortic valves, somewhat increase a murmur at the mitral valves, and somewhat increase a murmur at the tricuspid valves. But some further explanation was required, because all murmurs are not increased on recumbency and some are increased on recumbency although the antero-posterior diameter of the chest is unchanged. The action of gravity on the intra-cardiac currents then suggested itself as this further explanation. Professor Clifford Allbutt had pointed out that gravity seems to increase the venous hum in the neck in the erect position. A careful examination of the positions of the parts of the heart in the upright and recumbent positions appeared to indicate that gravity, when the recumbent position is assumed, should increase a mitral regurgitant murmur, increase a tricuspid regurgitant murmur, increase an aortic forward murmur, increase a pulmonary forward murmur, diminish a mitral forward murmur, and diminish an aortic regurgitant murmur. Now putting together the effects of gravity and variation in chest depth, Table III. shows: (*a*) what the combined influences of change in chest depth and changed relation to gravity might be expected to do; and (*b*) the changes in the murmurs which actually occur. It is interesting to note how closely *a* and *b* correspond. That gravity can considerably affect a fluid murmur is indicated by the following experiment. A round wide-mouthed bottle A (Fig. 6), 5 inches deep and 2½ inches wide, is fitted with a cork B, through which pass two glass tubes, C and D. D reaches to within 2 inches of the bottom of the bottle and is connected, outside the cork, by a short rubber tube E, with a rubber ball-syringe F. C ends just inside A and is connected outside by a long rubber tube G with the outflow pipe of a reservoir of water, so that when F has been emptied it can be refilled through A. The whole apparatus is filled with water, air-bubbles being excluded. If the bottom of A be placed against the ear and moderate pressure exerted by the hand on F a fluid murmur is heard. Let A be first held in Position 1 and let the pressure on F sufficient to produce a murmur be mentally noted. Then let A be held in Position 2 and the same pressure be applied to F. The murmur is louder and F is more easily and quickly emptied. *In both positions* A *must be held at the same level and just about that of the water in the reservoir, as a considerable counter-pressure of water in* A *naturally lessens the contrast between the observations in the two positions.*

TABLE III.—*Effects on Murmurs of Change from Erect to Recumbent Position.*

Form of murmur.	*a.* Probable effect of diminished antero-posterior diameter.	*a.* Probable effect of gravity.	*b.* Usual change.
Pulmonary *forward.*	Great increase.	Increase.	Great increase.
Tricuspid regurgitant.	Some increase.	"	Increase.
Mitral regurgitant.	" "	"	"
Aortic forward.	Decided increase.	"	"
Aortic regurgitant.	" "	Decrease.	No change.
Mitral forward.	Some increase.	"	Decrease or no change.

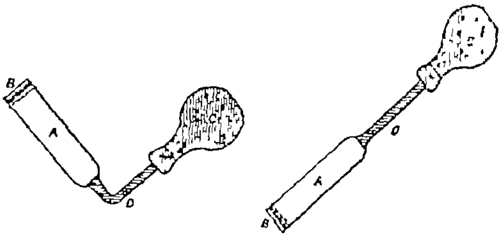
FIG. 6.



Position 1. Position 2.

Explanation of the changes in the normal sounds at the heart's apex.—As the influence of gravity helps to explain the changes in the murmurs it occurred to me that it might also help to explain the changes in the normal sounds. The explanation I have put forward is as follows. When the body is recumbent the blood in both ventricles is above the auriculo-ventricular valves, whilst the blood in the aorta and pulmonary artery is below the semilunar valves. On the other hand, when the body is erect the blood in both ventricles is below the auriculo-ventricular valves, whilst the blood in the aorta and pulmonary artery *is above* the semilunar valves. Possibly therefore a weight of blood resting on a set of valves tends to dull the sound of their closure. This explanation was supported by the following experiment.

FIG. 7.

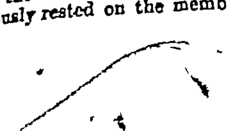


Position 1. Position 2.

A glass tube A (Fig. 7) three centimetres in diameter has one end open and the other drawn out to a neck. A membrane B of inelastic waterproof material is stretched not quite tightly over the broad end. The neck is connected with a ball syringe C, by a short length of rubber tubing D. The whole apparatus is filled with water so that a slight sudden pressure on C makes B suddenly tense and thus produces a sound. It will be found that when A is held in Position 1 with B upwards—i.e., with no weight of fluid on B—the sound is sharper that when A is held in Position 2 with B downwards—i.e., with a *certain* weight of water resting on B.

Objections to these last two explanations answered.—So far as the normal first sound and the regurgitant murmurs at the auriculo-ventricular orifices are concerned, it has been objected that the intra-ventricular systolic pressure *is so great* that it is hardly conceivable that gravity could affect the sounds.

Normal sounds.—My own want of precision in statement is responsible for the objection as regards the normal sounds. The weight which rests on the auriculo-ventricular valves in recumbency is not the whole weight of blood in the ventricles, but only that small part of it which the want of rigidity of the ventricular walls allows to rest on them. This weight is acting before systole begins and has the effect of making the valves already partially tense. Consequently when systole begins the completion of the tension of the valves cannot produce so sharp a sound as if no weight had rested on the valves so that they were quite relaxed at the moment when systole begins. A diagram (*Fig. 8*) will make clearer what I mean. In *Position 1* a weight of fluid has put a *membrane* slightly on the stretch in the position *a*; a sudden rise of pressure in the fluid then makes the membrane fully tense at *b*. The short movement *a* to *b* in Position 1 of the membrane already slightly stretched can scarcely be expected to give rise to so sharp a sound as the greater movement *c* to *d* of the membrane in Position 2 where no weight of fluid previously rested on the membrane which lay relaxed at *c*.



Britain. The well known radiant heat and light apparatus with its various accessories of the Dowsing Radiant Heat Company of 28, York-place, Baker-street, London, W., was shown ready for application. Mr. Alfred E. Dean of 82, Hatton-garden, London, E.C., exhibited some interesting and up-to-date apparatus for radio-therapy and light-therapy and Marconi's Wireless Telegraph Company of 18, Finch-lane, London, E.C., exhibited their induction coils, which are specially adapted for x ray and high-frequency treatment. Messrs. Browne and Sayer of 104, Upper Thames-street, London, E.C., with Messrs. Bale, Sons, and Danielsson, Limited, of Great Titchfield-street, London, W., exhibited the Osborne ideal bed-rest which is described as being cheap, portable, reliable, and efficient. The exhibit included Bale's well-known card index system of book-keeping, specially designed for the use of medical men, and an inhaler and a bed table. Lastly, Messrs. Reynolds and Branson, Limited, of 14, Commercial-street, Leeds, exhibited a new apparatus of some merit for the administration of oxygen, besides a number of surgical apparatus, including lamps for ophthalmic and throat work, bed bath, and bowel and stomach clamps.

II.—DRUGS.

The exhibition of drugs comprised many familiar friends chiefly of the synthetic order but there were some novel introductions worthy of note, while here and there was evidence of attempts to modify formulæ in accordance with clinical indications. The administration of iodine and bromine in the form of the old-fashioned bromides and iodides appears to be yielding in favour of organic compounds of these elements which, while giving the therapeutic effects of bromine and iodine, are claimed to be free from the phenomena known respectively as bromism and iodism. In the same way nitrate of silver threatens to be replaced by organic silver compounds and salicylate of soda by compounds containing the salicyl group but not attached to the alkaline metals. All this, of course, is of interest from a pharmaceutical point of view. The class of compounds just alluded to was very well represented in the exhibit of the Bayer Company, Limited, of 19, St. Dunstan's-hill, London, E.C. Here, for example, was aspirin, or aceto-salicylic acid, described as an ideal substitute for salicylate of sodium and as being free from the after effects of alkaline salicylates. The compound is not changed in the gastric juice but readily decomposes in the alkaline secretion of the intestine. Jothion is described again as an internal iodine preparation which may be substituted for potassium iodide administered internally. Sajodin is another iodine compound employed internally in the same quantity as is potassium iodide and is said to be free from the secondary effects known as iodism. The exhibit included somatose preparations both in the form of powder and of liquid. As we have pointed out before, somatose is a powerful nutritive. A very interesting series of preparations was shown by Meister Lucius and Bruning, Limited, of 51, St. Mary Axe, London, E.C. These comprised a number of sera, including the antistreptococcic serum of Hoechst, the diphtheria serum prepared by the Behring-Ehrlich method, the meningococcus serum, tetanus antitoxin, and the new tuberculin of Koch. Amongst the organic silver compounds were a compound of gelatose and nitrate of silver (albargin) used in the treatment of gonorrhœa and eye affections, and argonin, a casein silver salt. There was also a preparation known as valyl which is described as the active substance of valerian and indicated in nervous complaints and irregular and painful menstruation. Under the auspices of the Saccharin Corporation, Limited, of 165, Queen Victoria street, London, E.C., there were also shown at the same stall samples of novocain, described as a non-irritant local anæsthetic, exhibiting the same action as cocaine but without, it is said, the physiological drawbacks of that alkaloid. It is employed in ophthalmic and dental work and for producing lumbar or spinal anæsthesia. We have already drawn attention to the excellent cataplasm known as antiphlogistine. It is both antiseptic and hygroscopic and is a really scientific poultice. Samples were shown by the Denver Chemical Manufacturing Company, 41, St. Ann's road, Burdett-road, London, E. A series of modern therapeutic products of interest to the general practitioner was shown by Messrs. Parke, Davis, and Co., of 111, Queen Victoria-street, London, E.C. These included preparations of the active principle of the suprarenal gland, a local anæsthetic and ischæmic containing adrenalin and cocaine and known as "eudrenine"; a physiologically standardised preparation of ergot; and iodalbin giving, it is stated, the therapeutic effects of the iodides but without iodism. There were, besides, various sera and taka-diastase, a powerful starch-digesting agent. The exhibit of the Maltine Manufacturing Co., of 24 and 25, Hart-street, Bloomsbury, London, W.C., contained a useful number of preparations besides the well-known food products of Messrs. Carnrick and Co. Maltine is a liquid preparation of malt, having a powerful digestive action on starch, and is combined with various drugs—as, for example, the hypophosphites, iron, cascara sagrada, creosote, and so on. Maltine is also combined with cod-liver oil, the latter being obtained by a vacuum process which renders the oil pure and free from objectionable odour and taste. The stall of Messrs. Oppenheimer, Son, and Co., Limited, of 179, Queen Victoria-street, London, E.C., was attractively arranged and contained the specialities for which this firm is well known. As examples we may mention the hermetically sealed flask containers called aseptules, carrying accurate quantities of sterile preparations, amongst which we noticed normal saline solution, trypsin, ergot, sodium oleate, and extract of suprarenal gland. There were also illustrated the methods of administration of drugs by means of palatinoids and bi-plalatinoids. Further, there were shown hypodermic syringes and the "Universal Vaporiser." Petroleum appears to be an excellent vehicle for the administration of the hypophosphites and Angier's emulsion is, perhaps, the best example of such a preparation (the Angier Chemical Company, Limited, 32, Snow-hill, London, E.C.). This emulsion is stated to exert antiseptic, sedative, and demulcent effects along the intestinal tract. Milk of magnesia was the chief exhibit of the Charles H. Phillips' Chemical Company of 14, Henrietta-street, Covent Garden, W.C. It is, of course, a powerful antacid containing the hydrated oxide of magnesium. In addition to this preparation a "phospho-muriate of quinine compound" was shown containing the phosphates of potassium, magnesium, calcium, and iron, combined with the hydrochlorates of quinine and strychnine. Stovaine has already been described in these columns and referred to as a substitute for cocaine for producing anæsthetic effects. Many authorities have extolled its properties as a lumbar and spinal anæsthetic. Preparations of stovaine were shown by Mr. J. Flack, 16, Water-lane, Great Tower-street, London, E.C., who represents Les Etablissements Poulenc Frères of Paris. At the same stall were shown Billon's Ova-Lecithin, a definite organic phosphorus compound contained in eggs and said to be of great value in the treatment of wasting diseases. Atoxyl was also shown at this exhibit. It appears to be, according to Ehrlich, the sodium salt of paramido-phenyl-arsenic acid, and is now being tried as a remedy for sleeping sickness. The exhibit of Messrs. Armour and Co., of Atlantic House, Holborn Viaduct, London, E.C., was, of course, chiefly occupied by their well-known standard digestive ferments, including pepsin, pancreatin, and trypsin. The exhibit also included a crystalline form of adrenal substance and the same substance in the form of solution, powder, ointment, and "triturates."

Special pharmaceutical preparations standardised by physical, chemical, and physiological tests formed the subject of the exhibit of Messrs. Evans, Gadd, and Co., of Exeter. Amongst these may be mentioned the liq. violæ. glucosidi, a standardised preparation of the fresh leaves of the viola odorata. There was also a standard preparation of digitalis. Messrs. C. J. Hewlett and Son, of 35 to 42, Charlotte-street, London, E.C., exhibited a number of elegant misturæ, a pepsine and bismuth compound for gastrodynia, dyspepsia, &c. Besides these there was an excellent series of standardised concentrated liquors and some antiseptic preparations based on an approved formula. Messrs. B. Kuhn and Co., of 16, Rood-lane, London, E.C., exhibited specimens of the non-poisonous and non-irritant germicide chinosol, while there were some excellent preparations of papain, the vegetable pepsin. We have already described in our analytical columns the speciality of the Miol Manufacturing Co., Limited, of 66, Southwark Bridge-road, London, S.E. It is offered as a substitute for cod liver oil and contains olive oil, active malt extract, with medicinal doses of iodine and phosphorus.

Fine chemicals were well represented in the exhibit of Messrs. Knoll and Co. of 8, Harp lane, London, E.C. Bromural, for example, is an interesting bromine compound of the valerian group, combining the action of the bromides the same rule as that of mitral regurgitation but less constantly. I have figured a case in which it seemed little affected by posture, but in that case there was also adherent pericardium.

4. *Aortic regurgitation.*—Posture seems to have little effect on this murmur.

5. *Aortic stenosis.*—This murmur usually follows the same rule as the murmur of mitral regurgitation.

Explanation of the changes in the murmurs.—When looking for an explanation of the changes in the murmurs it occurred to me that, as most of the murmurs are increased on recumbency, perhaps the antero-posterior diameter of the chest might be less in that position. I found it was so. Then it seemed clear that this lessening of chest depth, by bringing the stethoscope relatively much nearer the pulmonary valves, relatively a good deal nearer the aortic valves, and relatively somewhat nearer the tricuspid and mitral valves, should greatly increase a murmur at the pulmonary valves, decidedly increase a murmur at the aortic valves, somewhat increase a murmur at the mitral valves, and somewhat increase a murmur at the tricuspid valves. But some further explanation was required, because all murmurs are not increased on recumbency and some are increased on recumbency although the antero-posterior diameter of the chest is unchanged. The action of gravity on the intra-cardiac currents then suggested itself as this further explanation. Professor Clifford Allbutt had pointed out that gravity seems to increase the venous hum in the neck in the erect position. A careful examination of the positions of the parts of the heart in the upright and recumbent positions appeared to indicate that gravity, when the recumbent position is assumed, should increase a mitral regurgitant murmur, increase a tricuspid regurgitant murmur, increase an aortic forward murmur, increase a pulmonary forward murmur, diminish a mitral forward murmur, and diminish an aortic regurgitant murmur. Now putting together the effects of gravity and variation in chest depth, Table III. shows: (*a*) what the combined influences of change in chest depth and changed relation to gravity might be expected to do; and (*b*) the changes in the murmurs which actually occur. It is interesting to note how closely *a* and *b* correspond. That gravity can considerably affect a fluid murmur is indicated by the following experiment. A round wide-mouthed bottle A (Fig. 6), 5 inches deep and 2½ inches wide, is fitted with a cork B, through which pass two glass tubes, C and D. D reaches to within 2 inches of the bottom of the bottle and is connected, outside the cork, by a short rubber tube E, with a rubber ball-syringe F. C ends just inside A and is connected outside by a long rubber tube G with the outflow pipe of a reservoir of water, so that when F has been emptied it can be refilled through A. The whole apparatus is filled with water, air-bubbles being excluded. If the bottom of A be placed against the ear and moderate pressure exerted by the hand on F a fluid murmur is heard. Let A be first held in Position 1 and let the pressure on F sufficient to produce a murmur be mentally noted. Then let A be held in Position 2 and the same pressure be applied to F. The murmur is louder and F is more easily and quickly emptied. *In both positions A must be held at the same level and just about that of the water in the reservoir, as a considerable counter-pressure of water in A naturally lessens the contrast between the observations in the two positions.*

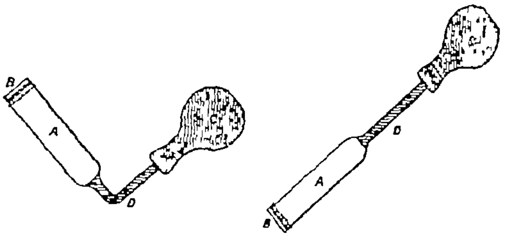
Position 1. Position 2.

Explanation of the changes in the normal sounds at the heart's apex.—As the influence of gravity helps to explain the changes in the murmurs it occurred to me that it might also help to explain the changes in the normal sounds. The explanation I have put forward is as follows. When the body is recumbent the blood in both ventricles is above the auriculo-ventricular valves, whilst the blood in the aorta and pulmonary artery is below the semilunar valves On the other hand, when the body is erect the blood in both ventricles is below the auriculo-ventricular valves, whilst the blood in the aorta and pulmonary artery is above the semilunar valves. Possibly therefore a weight of blood resting on a set of valves tends to dull the sound of their closure. This explanation was supported by the following experiment.

FIG. 7.



Position 1. Position 2.

A glass tube A (Fig. 7) three centimetres in diameter has one end open and the other drawn out to a neck. A membrane B of inelastic waterproof material is stretched not quite tightly over the broad end. The neck is connected with a ball syringe C, by a short length of rubber tubing D. The whole apparatus is filled with water so that a slight sudden pressure on C makes B suddenly tense and thus produces a sound. It will be found that when A is held in Position 1 with B upwards—i.e., with no weight of fluid on B—the sound is sharper that when A is held in Position 2 with B downwards—i.e., with a certain weight of water resting on B.

Objections to these last two explanations answered.—So far as the normal first sound and the regurgitant murmurs at the auriculo-ventricular orifices are concerned, it has been objected that the intra-ventricular systolic pressure is so great that it is hardly conceivable that gravity could affect the sounds.

Normal sounds.—My own want of precision in statement is responsible for the objection as regards the normal sounds. The weight which rests on the auriculo-ventricular valves in recumbency is not the whole weight of blood in the ventricles, but only that small part of it which the want of rigidity of the ventricular walls allows to rest on them. This weight is acting before systole begins and has the effect of making the valves already partially tense. Consequently when systole begins the completion of the tension of the valves cannot produce so sharp a sound as if no weight had rested on the valves so that they were quite relaxed at the moment when systole begins. A diagram (Fig. 8) will make clearer what I mean. In Position 1 a weight of fluid has put a membrane slightly on the stretch in the position *a*; a sudden rise of pressure in the fluid then makes the membrane fully tense at *b*. The short movement *a* to *b* in Position 1 of the membrane already slightly stretched can scarcely be expected to give rise to so sharp a sound as the greater movement *c* to *d* of the membrane in Position 2 where no weight of fluid previously rested on the membrane which lay relaxed at *c*.

Liverpool; Cecil John Rogerson, University College; Mary Schofield and Mary Cowper Scott, London (Royal Free Hospital) School of Medicine for Women; *†‡§ Clement Edward Shattock, University College; Charles Woolley Shepherd, University College, Cardiff; Frederic Carney Shone, University College; Bernard Sangster Simmonds, Middlesex Hospital; *†Thomas Duncan Macgregor Stout, Guy's Hospital; John Bailey Tackaberry, Middlesex Hospital; Harold Herbert Tanner, St. Mary's Hospital; Norman Tattersall, Victoria University of Manchester; †George Taylor, London Hospital; Gottfried Oram Teichmann, Middlesex Hospital; ‡William Rees Thomas, University College, Cardiff; Henry Ashbourne Treadgold, University of Cambridge; Thomas Anger Fereman Tyrrell, St. Mary's Hospital; Philip John Veale, University College, Bristol; Theodore Henry Whittington, King's College; and James Cowan Woods, London Hospital.

The following candidate having qualified in organic chemistry has now completed the intermediate examination in medicine:—

James Rocheid Forrest, University College and St. Bartholomew's Hospital.

* Distinguished in anatomy. † Distinguished in physiology.
‡ Distinguished in pharmacology.

‖ Bracketed equal for scholarship in physiology.
¶ Bracketed equal for scholarship in anatomy.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

LONDON SCHOOL OF TROPICAL MEDICINE.—At the London School of Tropical Medicine last week Mr. Percival A. Nairne (chairman of the Seamen's Hospital Society) unveiled a portrait of the Hon. Bomanji Dinshaw Petit, one of the most munificent benefactors of the school. Mr. Nairne, having recapitulated the events which led to the establishment of the school, said that Sir Francis Lovell undertook a mission to the East at the request of the Colonial Office to make known the objects at which the promoters of the school aimed. While in Bombay he met Mr. Petit who, explaining his motives as being due equally to humanity and a desire to cement a union of hearts between the East and the West, gave the school a lac of rupees (about £7000). Sir Patrick Manson said that a great city like London should not have had to go to Bombay for assistance in such matters. But for Mr. Petit's gift the work of the school would have been very much cramped and brought into danger of an abrupt conclusion. Good progress was now being made in the tutorial department. They had three chairs in connexion with tropical medicine and assurances from the Government that two of them would be continued for a period of five years. Mr. Dhunjeebhoy Petit (Mr. Dinshaw Petit's son) said that his father's greatest reward in making the gift was the betterment of the suffering multitudes of India that would result from the working of the school. Sir M. Bhownaggree, in moving a vote of thanks to Mr. Nairne, said that the school would be a symbol of that union of hearts which patriotic men like Mr. Dinshaw Petit wished to see grow up between Great Britain and her Eastern Empire.—The following students of the London School of Tropical Medicine successfully passed the examination in the different subjects comprised under the head of tropical medicine at the end of the session:—

*A. W. Balch, Surgeon United States Navy, Ph.G. Mass., M.D. Harvard; T. P. Beale-Browne, M.R.C.S. Eng., L.R.C.P. Lond. (Colonial Service); J. C. C. Ford, L.R.C.P. & S. Edin., L.F.P.S. Glasg. (Colonial Service); *C. A. Godson, I.M.S., M.R.C.S. Eng., L.R.C.P. Lond.; *F. Grenier, M.B., C.M. Edin. (Colonial Service); F. C. Hepburn, M.R.C.S. Eng., L.R.C.P. Lond., B.A. Cantab. (Colonial Service); *Captain F. H. G. Hutchinson, I.M.S., M.B., C.M. Edin., D.P.H. Camb.; K. McMurtrie, M.B., Ch.B. Edin.; *Captain J. N. Walker, I.M.S., M.R.C.S. Eng., L.R.C.P. Lond.; E. Weatherhead, M.B. Cantab., M.R.C.S. Eng., L.R.C.P. Lond. (Colonial Service); G. Wilkinson, M.B., B.C. Cantab., L.S.A.; and *Captain W. S. Willmore, I.M.S., M.R.C.S. Eng., L.R.C.P. Lond.

* Passed with distinction.

UNIVERSITY OF EDINBURGH.—The following degrees and certificates were conferred on July 26th:—

Doctor of Medicine.—‡Edward Archer-Brown, M.B., Ch.B., South Africa (*in absentiâ*); ‡John Henry Montgomerie Bell, M.B., Ch.B., Scotland (*in absentiâ*); *Lesley Newton Hesketh Biggs, M.B., Ch.B., India; ‡George John Blackmore, M.B., C.M., New Zealand (*in absentiâ*); ‡Thomas Charles Blackwell, M.B., Ch.B., England; ‡Richard Alfred Blake, M.B., Ch.B., England (*in absentiâ*); William Dudley Boswell, M.B., Ch.B., England; †Orlando Charnock Bradley, M.B., Ch.B., England (with Second-class Honours); Alfred Brown, M.B., Ch.B., Scotland; Herbert Maughan Brown, M.B., Ch.B., England; †Hablot John Moxon Browne, M.B., C.M., England; ‡Alfred Ernest Burroughs, M.B., Ch.B., Scotland; ‡Katherine Jane Stark Clark, M.B., Ch.B., Scotland; Paula Theodora Copeland, M.B., Ch.B., Scotland (with First-class Honours); ‡Robert William Craig, M.B., Ch.B., Scotland; ‡John Crawford, B.Sc., M.B., C.M., Scotland; Peter Crerar, M.B., C.M., Scotland; John Edward Twiston Davies, M.B., C.M., Wales; ‡David Ewart, M.B., Ch.B., New Zealand (with Second-class Honours); Francis Edwin Field, M.B., Ch.B., British Guiana; Samuel Bradley Figgis, M.B., C.M., England; Gerald Hall Lloyd Fitzwilliams, M.B., Ch.B., Wales; John Fortune, M.B., Ch.B., Scotland; ‡Lawson Gifford, M.B., C.M., Jamaica (*in absentiâ*); ‡Norman Gregg, M.B., Ch.B., Scotland; John Ligertwood Green, M.B., Ch.B., Scotland; *James Andrew Gunn, M.A., B.Sc., M.B., Ch.B., Scotland (with First-class Honours); ‡William Hamilton, M.B., Ch.B., Ireland; ‡Philip Anthony Harry, M.B., Ch.B., Jamaica; William Hume, M.B., Ch.B., Australia; ‡Harold Kerr, M.B., Ch.B., Scotland; Langworthy Laurie, M.B., Ch.B., England (with Second-class Honours); Charles George Stretton, Leeds, M.B., Ch.B., England; William Leslie, M.B., C.M., Scotland; *James Lochhead, M.A., B.Sc., M.B., Ch.B., Scotland (with First-class Honours); *Stuart M'Donald, M.B., C.M., Scotland; ‡William Chisholm Wilson M'Dowell, B.A., M.B., C.M., New Zealand (*in absentiâ*); Robina Harlin *née* M'Gregor, M.B., Ch.B., Scotland (with Second-class Honours) (*in absentiâ*); †Neil M'Vicar, M.B., C.M., Scotland (with First-class Honours) (*in absentiâ*); Alexander Mowatt Malcolmson, M.B., Ch.B., Scotland; †William Joseph Maloney, M.B., Ch.B., Scotland (with First-class Honours); William Miller, M.B., Ch.B., Scotland; ‡Harley Patterson Milligan, M.B., Ch.B., England; ‡Robert Unwin Moffat, M.B., C.M., South Africa; ‡Richard Caldecott Monnington, M.B., Ch.B., England; Harold Mowat, M.B., Ch.B., Scotland; ‡Hugh Lennox Munro, M.B., Ch.B., Scotland (with Second-class Honours); †James Hunter Harvey Pirie, B.Sc., M.B., Ch.B., Scotland; ‡Charles Frederick Ponder, M.B., C.M., Scotland; Andrea Francis Honeyman Rabagliati, M.B., Ch.B., England (*in absentiâ*); Hugh Smith Reid, M.B., Ch.B., Scotland; †Lionel Charles Peel Ritchie, M.B., Ch.B., Scotland; ‡Thomas Ronaldson Smith, M.B., Ch.B., Scotland; ‡William Arthur Wilson Smith, M.B., Ch.B., Scotland; ‡Ralph Stuart Stephenson, M.B., C.M., New Zealand; †Herbert Jamieson Stewart, M.B., Ch.B., Australia (*in absentiâ*); *Hugh Angus Stewart, M.B., Ch.B., Scotland; ‡Arthur Charles Strain, M.B., Ch.B., Scotland (with Second-class Honours); ‡James Prain Sturrock, M.A., M.B., C.M., Scotland; ‡William Dunbar Sutherland, M.B., C.M., India; John Thomarson, M.B., C.M., England; Edward Francis Valenzia, M.B., Ch.B., Egypt; Syed Mohamed Varis, M.B., C.M., India (*in absentiâ*); †Robert M'Leod Veitch, M.B., Ch.B., Scotland; *Henry Wade, M.B., Ch.B., Scotland (with Second-class Honours); Hubert Clinton Weber, M.B., Ch.B., British Guiana; John Henry Douglas Webster, M.B., Ch.B., Scotland; William Ebenezer Caradog Williams, M.B., C.M., Wales; and Gerald William Young, M.B., Ch.B., England.

Master of Surgery.—‡Samuel Evans, M.B., C.M., India; and †Duncan Campbell Lloyd Fitzwilliams, M.D., Wales.

* Awarded Gold Medals for their Theses. † Highly commended for their Theses. ‡ Commended for their Theses.

Bachelor of Medicine and Master in Surgery.—Stephen Rowland, England.

Bachelor of Medicine and Bachelor of Surgery.—George Joseph Adams, England; ‖John Budge Alexander, M.A., Scotland; John Laing Annan, Scotland; Alfred Arthur, Ireland; ‖John Caradoc Ashton, Wales; Robert George Archibald Bagnall, England; David Malcomson Barcroft, Ireland; Abraham Cockcroft Barker, England; Charles Botterill Baxter, England; ‖Albert Edward Bennee, South Africa; Mary Florence Bignold, England; Herbert Walter Binks, England; Francis George Hamilton Rollo Black, England; James Allan Brand, Scotland; Alexander Bremner, Scotland; James Brennan, Ireland; Hugh Francis Briggs, England; David Stirling Buist, Scotland (*in absentiâ*); Thomas Burrell, Scotland; Percival Douglass Cameron, Scotland; John Raymond Chapman, England; William David Coghill, Scotland; Claude Ernest Addison Coldicutt, New Zealand; Charles Henry Corbett, England; Theodore Craig, Scotland; Francis William Murray Cunningham, Scotland; Cornelius Hildebrand Derksen, South Africa; Thomas Derrick, Scotland; Pollok Donald, Scotland; Mackenzie Douglas, M.A., Scotland; George Laurence Duncan, Scotland; ‖Pieter Abraham Euvrad, Cape Colony; Vaughan Lloyd Evans, Wales; Josephine Letitia Denny Fairfield, England; Sydney Boyd Faulkner, Scotland; William Pike Ferguson, M.A., B.Sc., Scotland; Mary Struthers Finlayson, Scotland; William Smith Forbes, Scotland; ‖John Fraser, Scotland; Oney Mortimer Gericke, Cape Colony; John Boyd Gibson, M.A., Scotland; Robert Macnaught Glover, Scotland; Ian Mount Grant, Scotland; David George Gray, Ireland; Andrew Rugg Gunn, Scotland; ‖Douglas James Guthrie, Scotland; §George Henderson, Scotland; Nettie Dick Hendrie, Scotland; William Samuel Heron, Ireland; Andrew Fergus Hewat, Scotland; Aubrey Middleton Hewat, Scotland; Matthew Heyns, Cape Colony; James Rowland Hill, Ireland; Jan Kriel Albertyn Hofmeyr, B.A., Cape Colony; ‖John Howard Horne, Scotland; Alexander Hunter, Scotland; John Alexander Jamieson, Scotland; §Robert Hillhouse Jamieson, Scotland; William Wilton Johns, Wales; Reginald Fitzherbert Johnson, British Guiana; Blanche Mary Zillah Johnston, England; Matthew James Johnston, Ireland; §Thomas Arnold Johnston, Ireland; William David Stoney Johnston, New Zealand; Daniel Johnstone, M.A., Scotland; Gordon Gray Jolly, Scotland; Schalk Willem Joubert, Cape Colony; John Henry Lamb, England; John Howard Lechler, India; Alaister Fraser Lee, Scotland; David Lees, M.A., Scotland; Carl Wilhelm Ludwig Luethgen, Germany; William Simpson M'Cune, Ireland; Angus Macdonald, Scotland; William Kelman Macdonald, Scotland; Alister Thomas Mackenzie, M.A., Scotland; ‖Rory Eric M'Laren, Scotland; Helen Meldrum M'Millan, Scotland; John Alexander Manifold, England; Legh Richmond Herbert Peter Marshall, Scotland; Ada Elizabeth Miller, Scotland; Margaret Mair Miller, Scotland; Charles Irvine Milne, Scotland; Charles James Milne, Trinidad; Alexander Philip Mitchell, Scotland; James Arthur Morris, Scotland; John Morrison, Scotland; James Muckhart, Scotland; §John Joseph Harper Nelson, Scotland; §Charles Fulton Pattie, New Zealand; ‖William James Porteous, Scotland; Denis Eldred Curwen Pottinger, England; Norman Henry Prior, New Zealand; *Dewan Hakumat Rai, M.A., India (*in absentiâ*); Charles Robertson, B.A., Scotland; ‖David Robertson, Scotland; William Stewart Irvine Robertson, Scotland; Walter Alexander Scobie, Scotland; James Scott, Scotland; Ralph Leicester Scott, England; Alice Cameron Sharp, Scotland; Wilfred James Simpson, Scotland; Ernald Dryborough Smith, Scotland; Fleet Floyd Strother Smith, Ireland; Dorothy Wilhelmine Stevenson, Scotland; Lewis Hay

FURTHER RESEARCHES INTO THE ETIOLOGY OF CARCINOMA: NOTE UPON CERTAIN HISTOLOGICAL FEATURES OF CARCINOMATOUS TUMOURS REVEALED BY AN IMPROVED AMMONIO-SILVER PROCESS.

BY W. FORD ROBERTSON, M.D. EDIN.,
PATHOLOGIST TO THE SCOTTISH ASYLUMS;
AND
M. C. W. YOUNG, M.B., CH.B. EDIN.

TWO and a half years ago there was published in THE LANCET a paper by Mr. Henry Wade and one of us[1] in which it was contended, on the ground of observations recorded, that carcinomatous tumours are etiologically related to a special protozoan organism, capable of being demonstrated in such tumours and cultivated from them. In the course of researches carried out during the past year, we have obtained much new evidence that we regard as confirmatory of this view. This evidence has been derived both from cultural and histological observations. We shall deal here only with the latter; the former have not been devoid of further definite results, but on account of certain difficulties of interpretation that have arisen we wish to repeat and to extend the experiments before making any communication regarding them.

As is well known, the view that carcinomatous tumours are of parasitic origin, at one time strongly advocated, has of late years fallen into disfavour owing to the inability of most observers to obtain convincing evidence of the presence of any special parasites and for other reasons. There are, however, signs that the question of the etiology of these tumours is now entering upon a new phase in which the investigations that will add materially to our knowledge of the subject will be concerned mainly with the study of certain special micro-organisms now demonstrable in the tissues, the cultivation of these parasites and their destruction by vaccine and serum-therapeutic methods.

Gaylord, Clowes and Baeslack[2] have shown that a large percentage of tumours produced in mice by inoculation of Jensen's adeno-carcinoma undergo spontaneous retrogression and disappear. They were the first to obtain extensive evidence of this fact, though it had been observed previously by Michaelis and Apolant. They have, moreover, shown that mice which have thus spontaneously recovered cannot be successfully reinoculated. The conclusions of these American workers were at first seriously questioned, but have now been fully confirmed. There are at present many who endorse their opinion that these phenomena of spontaneous retrogression and immunisation are best explained on the view that there is a living virus concerned in the production of these tumours which is capable in certain instances of being successfully combated by the protective forces of the host. Gaylord[3] has reported some observations showing that infected cages may be a source of spontaneous cancer in rats and mice. Ehrlich[4] has observed the transformation of the adeno-carcinoma of the mouse into a sarcomatous tumour, an occurrence which would be satisfactorily explained by such growths being dependent upon infection of the tissues by a special micro organism. Schüller[5] has recently, in confirmation of previous contentions, maintained that he has been able, with the aid of a special double staining method, to demonstrate the presence of certain parasitic bodies in the nuclei of the proliferating cells of carcinomata and sarcomata. It seems probable that these bodies are identical with the "granular phase" described in the previous paper in THE LANCET as having been found especially in the cells of a malignant adenoma of the intestine and shown in one of the photographs (Fig. 5) illustrating that communication. Gaylord,[6] in a paper published a few months ago, has described a special spirochæta in primary and transplanted carcinoma of the breast in mice. This organism differs from the spirochæta microgyrata of Löwenthal and from the organisms found by Borrel in mouse tumours, in respect of the fact that it is not coloured by the Giemsa stain. It is best revealed by Levaditi's method which shows it as a characteristic spiral organism from 2·5 to 2·8 μ in length and 0·6 μ in width, with from 4 to 13 turns per individual. These spirochætæ were found in ten consecutive spontaneous carcinomata of the breast in mice obtained from various districts, and in all of 16 transplanted mouse tumours examined. Gaylord states that they occur chiefly in the most actively growing portions of the tumour and live in the connective tissues at the margin of the growth and in the stroma, but also between the epithelial cells and in cyst cavities where these are present. The organisms are also occasionally found in the protoplasm of the epithelial cells, and their presence in this situation is regarded by Gaylord as an evidence of phagocytosis on the part of the tumour cells. He recognises that his observations do not as yet establish an etiological relation between these spirochætæ and cancer of the breast in mice. Gary N. Calkins,[7] in a paper published at the same time, names these organisms spirochæta microgyrata (Löwenthal) var. Gaylordi. He finds that the average length of the node (the part from the crest of one undulation to the crest of the next adjacent) is 0·6 μ, and considers this fact at the present time the most satisfactory basis for the identification of the organism. This spirochæta is also 0·6 μ in width and therefore the nodes are characteristically crowded and the undulations steep. Compared with spirochæta Obermeieri, spirochæta refringens, and spirochæta pallida, it has more crowded nodes and a greater diameter, both relatively and absolutely. The ends are blunt and rounded, and there is no evidence of tapering at the extremities, of undulating membrane, or flagella. The closing paragraph of Calkins's paper is of special interest in connexion with the observations we are about to record, and we therefore quote it in full: "Various enigmatical structures are found in the nuclei of the epithelial cells of these primary cancers—structures which I have failed to find in any of the normal glandular tissue which has been treated in the same way as the cancer tissue (i.e., by the Levaditi silver impregnation method). For this comparison I have examined carefully tissue from thyroid, liver, intestine, and, in addition, mesentery connective tissue and muscles, all from normal mice, and in no case have I found the organism or intranuclear bodies mentioned above. In a future publication I hope to be able to throw some light on the significance of these intranuclear structures."

Our own recent histological observations have been essentially a continuation of those already recorded in THE LANCET. We have made numerous experiments with a view to improving the ammonio silver process. Distinct advances as regards the clearness of the histological pictures have been obtained by stronger silver impregnation and by the employment of various agents which partially remove either the silver deposit or the gold which has replaced it. For the removal of the silver deposit platinum bichloride has been of most service; for the removal of the gold deposit potassium cyanide has been used. A still further and very striking improvement has recently been effected by fixing the tissues with corrosive sublimate. The necessary directions for the carrying out of this improved ammonio-silver process are given below.

The general result of these new investigations has been to obtain a considerable amount of additional evidence of the occurrence of special intranuclear bodies of the nature of those previously described, to show that structures morphologically identical with the spirochæta microgyrata can be demonstrated in human carcinomata, and to confirm the previous observation of the occurrence of small nucleated bodies, evidently of amœboid character, in such tumours. We have also to record some observations upon the Jensen mouse tumour, including that of the presence of a body morphologically identical with the spirochæta described by Gaylord and Calkins. We shall first briefly describe the appearances presented in some tumours of which specially successful preparations have been obtained.

1. *Squamous epithelioma (anus). Removed by operation. Received from Mr. Henry Wade. Ammonio-silver process,*

---

clerk of the Privy Council was received stating that the proposed amendment of Clause 2 (4) of the Notification of Births Bill did not commend itself to the Lord President. A letter was considered from Dr. R. P. Ranken Lyle as to ignorance of the rules shown by candidates at the recent examination in Newcastle and inquiring whether examiners should reject candidates on this ground alone. The Board decided that Dr. Lyle should be informed that as candidates were bound to know the rules (Rule O 4 (i.)) it was the duty of the examiners to ascertain that they did. Further, the secretary was directed to call the attention of the training schools involved to the necessity of adequately instructing their pupils in the rules as required by Rule O 4 (i.). A letter was received from Dr. J. J. Buchan, medical officer of health, St. Helens, forwarding a copy of a scheme adopted by the local supervising authority for the payment of medical practitioners sent for in cases of emergency to assist midwives. The Board decided that Dr. Buchan should be thanked for the care and trouble which he had taken in compiling the scheme, which it was hoped might lead to the difficulty being similarly dealt with in other places. A letter was read from a midwife as to the refusal of a parish medical officer to attend when sent for in a case of emergency. The Board decided that the midwife should be informed that a midwife has discharged her responsibility in advising that medical assistance should be sent for, and that when the patient is unable to pay a medical man's fee she should send directly to the district medical officer.

MEDICAL CRICKET MATCH.—A cricket match was played on the Gloucestershire county ground, Bristol, on July 26th, between two teams selected from the medical staff and students of the Royal Infirmary and General Hospital. After an interesting game the medical students won by four wickets.

THE INSTITUTE OF HYGIENE.—Lord Robert Cecil held a reception at the Institute of Hygiene on July 26th, which was largely attended by members of the medical profession. The exhibition room and lecture hall were very crowded at times but the guests found much to interest them in examining the various foods and beverages on exhibition as well as in the demonstrations of new appliances and machines in the hospital section.

LIVERPOOL CONVALESCENT INSTITUTION: ANNUAL MEETING AT WOOLTON.—*The thirty-third* annual meeting of the subscribers to the Liverpool Convalescent Institution took place on July 13th in the Gladstone Hall of the beautiful retreat at Woolton. The Lord Mayor of Liverpool occupied the chair. The report of the council embodied a satisfactory statement of progress, as is shown by the following summary. Judging by the statistics relating to the admissions of patients, the purpose for which the institution was originally established has been appreciated in greater measure each year. The best proof of recognition by the public of an institution such as that was the increasing use made of it. In applying that test it was seen that there had each succeeding year been stronger testimony to the regard in which it was held by the classes for whose health and restoration it was in the first instance thought to be desirable. In the year just closed the record of the total of patients was the highest known. During the 12 months no fewer than 2956 patients were admitted, compared with 2732 in 1905 and 2305 in 1896, showing in the period between 1896 and 1906 an increase in admissions to the extent of 651. Such an accession to the number of patients afforded complete satisfaction and confirmed the anticipation that the more general use of the scheme of nomination and recommendation by subscribers would justify the hope entertained at the time when the system came into vogue—viz., that the outcome would be a widening of the area over which the benefits of the institution had hitherto extended. So steady had been the demand for admission during the year that the accommodation had been extended by ten additional beds. In 1900 the amount received in yearly subscriptions was £966, whereas in 1906 £1192 were subscribed. Amongst the special donations were the following: Liverpool Hospital Sunday and Saturday Fund, £371; Liverpool Theatrical Football Gala Committee, £100; Mr. G. S. Goodwin, £50; Sefton Park Presbyterian Church, £23, with other sums totalling £40. Sir James Barr, in seconding a vote of thanks to the ladies' committee, said that he was very pleased to see that the ladies took such an interest in that important institution. A great deal of good was done by them; in fact, to their work was largely to be attributed the success achieved by such institutions.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Royal Assent.

AMONGST the Acts of Parliament which received the Royal Assent on Friday, July 26th, were the King Edward's Hospital Fund for London Act and the Alton Military Hospital Act.

The Prospects of Private Members' Bills.

The remaining weeks of the Parliamentary session in the House of Commons have, by a resolution passed on July 26th, been allocated to the dispatch of Government business. No Bills introduced by private Members can be advanced even after 11 o'clock at night unless they are adopted by the Government. In this way are the chances extinguished of the vast majority of private Members' Bills reaching the Statute book this session. The Government, having a heavy programme of its own to push forward, is little likely to load it still more with the measures promoted by private Members of the House. It is hoped that it may, however, be induced to adopt two or three Bills which have made considerable progress in the House by its goodwill but for which it is not responsible. In particular the claims of the Notification of Births Bill are being urged for preferential treatment in this respect. Lord ROBERT CECIL, who introduced the Bill, readily assented in Committee to modifications in the text of the measure to satisfy the Local Government Board. Some opposition to its details is threatened on report and doubtless the extent of this will determine the decision of the Government whether it will grant it special facilities. Sir JOHN BATTY TUKE and Sir HENRY CRAIK have given notice of an identical motion for the recommittal of the Notification of Births Bill. It runs thus: "That the Bill be recommitted for the purpose of amending it in several respects, particularly by striking out the provision that medical practitioners and midwives should be compelled to furnish the notification in question under penalties and without fee or reward."

The Post Office and Medical Men.

Several paragraphs in the report of the Select Committee of the House of Commons on Post Office servants deal with the relations of that department with its medical officers. Medical officers attached to post-offices in the United Kingdom number about 3000 and are all unestablished. The report states that they hold their appointments at the pleasure of the Post-Master General and can be removed or retire without receiving or giving notice. Complaint was made to the Committee with regard to the recently introduced regulation by which medical officers are bound to retire at the age of 70 years, and it was claimed that the regulation should be confined to future appointments only. The Committee does not recommend any alteration in the Post-Master General's circular respecting the age of retirement, although it observed that this might have been advantageously fixed at 65 years. It is further of opinion that the report on the efficiency of the medical officers should be the actual work of the surveyor himself subject to an appeal to the chief medical officer. It regards the present fee of 8s. 6d. per head for medical treatment as sufficient in the case of members of the staff not on the regular list as well as those on it. The Committee recommends that in future the fee for the entrance examination of established men should be 10s. each, to include any subsequent examination during probation. It reports against placing medical officers on the establishment. In another portion of its report the Committee expresses the opinion that greater attention should be paid to the sanitary requirements of the Post Office staff. It further states that it is "of opinion that it is improper for a civil servant in the position of chief medical officer of the Post Office to hold such a position as medical officer to civil service stores." However, it recognises that Dr. WILSON had obtained authority to hold these appointments. It recommends that it should be part of the regular duty of the head-quarter medical staff from time to time to pay surprise visits of inspection and to report on the principal offices in London and the provinces. For the adequate performance of this duty some of its officers should hold approved diplomas in sanitary science or public health.

The Government's Programme.

Sir HENRY CAMPBELL-BANNERMAN in making a statement as to the business to be taken in the remaining weeks of the Parliamentary session mentioned the Bills which the Government did not intend to proceed with. These included the Poisons and Pharmacy Bill, the Lunacy (Ireland) Bill, and the Municipal Milk Depôts Bill. He went on to state that there were a number of Bills which the Government hoped to be able to pass, but which, if they were keenly opposed, could not be proceeded with. These included the Education (Scotland) Bill, which contains clauses dealing with the feeding of necessitous cells contain numerous black spherical bodies, identical with those described in the preceding case (Fig. 2). Similar bodies occur locally between the epithelial cells and among the connective tissue. No thread or spiral forms have been detected, but a few amœboid forms have been seen. Processes of phagocytosis seem to be in abeyance.

3. *Very rapidly growing squamous epithelioma (foreskin). Removed by operation. Sent by Dr. R. B. Campbell of Inverness District Asylum. Formalin fixation, ammonio-silver process, gold-tungstate toning, cyanide decolourization.*—Black spherical bodies, identical with those already described, are present in the nuclei of many of the epithelial cells, but there are rarely more than three or four in one nucleus. Many cells do not contain any. Similar cyanide-fast bodies can be seen lying in the spaces between the epithelial cells. There are abundant polymorphonuclear leucocytes among the adjacent connective tissues and locally among the epithelial cells; most of them are loaded with the cyanide-fast bodies in various stages of disintegration. Some twisted thread-like bodies, similar to those described in Case 1, have been observed among the connective tissues. In the nucleus and protoplasm of the epithelial cells, between the epithelial cells, and in the connective tissues numerous examples of bodies morphologically identical with the spirochæta microgyrata have been detected, but composed of rarely more than three or four nodes.

4. *Secondarily infected mesenteric lymphatic gland from a case of malignant adenoma of the intestine. Removed by Dr. F. M. Caird. Formalin fixation, ammonio-silver process, palladium-gold toning.*—Some of the histological features presented by this tissue, more especially the granules in the nuclei, were described in the previous paper. In some of the pieces examined the nuclei of the epithelial cells contain from six to 12 or more black spherical bodies, morphologically identical with those described in the foregoing cases (Fig. 3). Similar bodies are sometimes to be seen in the nuclei in the connective-tissue corpuscles. They occur also in the protoplasm of the epithelial cells and are fairly abundant in the spaces of the surrounding connective tissues. There is marked phagocytic activity on the part of the polymorphonuclear leucocytes, which commonly contain similar black granules. Spiral forms have not been recognised within the nuclei of the cells, but they are fairly common in the connective-tissue spaces. In one set of sections they are locally very abundant (Fig. 10). Many of the preparations from this case show the supposed amœboid bodies. These occasionally assume an elongated form with knob-like extremities; such bodies were also described and figured in the previous paper as occurring in this tumour.

5. *Malignant adenoma of breast. Removed by Dr. David Wallace. Sublimate fixation, ammonio-silver process, gold-tungstate toning, cyanide decolourization, re-toning with gold-tungstate solution.*—The most striking feature in the preparations from this case is the presence in the protoplasm of very many of the epithelial cells of numerous bodies of the nature of the supposed amœboid bodies already described as occurring especially in Case 1. They differ, however, in having generally a spherical instead of an irregular outline (Fig. 7). This difference may be accounted for by the fact that they are lying within the protoplasm of a cell instead of in a lymph space. From one to 20 may occur in a single cell. In many of the sections they are the only structures that have resisted the action of the cyanide, everything else being colourless. The most common form is that of a finely granular rounded body about 2 μ in diameter containing a minute black dot, generally eccentric in position. Some of the smaller forms, commonly oval in shape, are outlined by a dark band, internal to which there is a clear space and at one end a black granule (Fig. 7). Some of the larger forms contain numerous cyanide-fast bodies, identical with the black spheres already described in the other cases. Some thread-like forms, similar to those seen in Case 1, have been observed, but no spiral bodies have been detected.

Appearances similar to those described in these five tumours have been observed with less distinctness in very numerous other carcinomatous growths, fixed in formalin and prepared for examination in accordance with an earlier technique. Various normal and morbid tissues have also been studied as controls. The black spheres in the nucleus are not a normal feature of either squamous or glandular epithelium. In morbid tissues there are, as might be expected, many degenerative granules which hold on to the gold deposit with considerable tenacity, and among these there are especially certain fatty granules. As a rule, however, these are easily distinguished from the bodies we have described.

We have also examined by our new method an adenocarcinoma of a mouse (Jensen's tumour) kindly supplied to us by Mr. Wade. The tumour had been hardened in formalin. In a set of preparations from a rapidly growing portion of the growth appearances are presented very similar to those we have described in human carcinomata. Over extensive areas the nuclei of nearly all of the epithelial cells contain several cyanide-fast bodies, occurring as single spheres, in pairs, and in short chains (Fig. 9). In some instances the black granule appears to be contained within a paler structure of irregular outline. In these preparations the chromatin of dividing cells is stained red and the black spheres can be seen to persist during the mitosis of the cells. Similar bodies are occasionally to be observed in the protoplasm of the cells (Fig. 9) and in the surrounding connective tissues. In all of these tissues forms may occasionally be detected which have the morphological characters of the spirochæta microgyrata, excepting that the number of nodes rarely exceeds two or three.

Several questions arise in regard to these histological features that we have described. The first naturally is, What are the *cyanide-fast bodies*? They are certainly not normal structures and it is at least extremely improbable that they are merely degenerative products. They occur especially in the rapidly dividing tumour cells, they have certain regular forms which are repeated in successive tumours, and they have not been found in other pathological conditions. Numerous observed facts support the view that they are stages of a special protozoan organism. They appear to undergo proliferation; the spherical forms commonly occur in pairs and not infrequently as short chains. The bodies of the form of the spirochæta microgyrata and those that have the appearance of minute nucleated amœbæ cannot be explained away as degenerative products. The strong chemiotactic attraction that is manifested by the polymorphonuclear leucocytes towards these special bodies could hardly be developed towards any simple degenerative product, but might quite well be exhibited towards a special parasite. Agar cultures made from the malignant adenoma of the intestine show certain spherical bodies, evidently proliferating and advancing into the medium, as described in the former paper. We have recently tested these bodies in sections of the agar medium and find that they are cyanide-fast, like the bodies observed in carcinomatous tissues.

If it is admitted that these bodies are parasites the next question that arises is, Are they spirochætæ? If they are spirochætæ such organisms have a much more complicated cycle than has been supposed, for it is pretty clear that the spherical intranuclear bodies, the threads, the spirals, and the amœboid forms, are all stages of the same structure. There is some ground for questioning that the supposed spiral is always really of this form. In examples such as those shown in Figs. 5, 6, and 9 this form occurs almost beyond a doubt. It is different, however, in the case of the bodies shown in Fig. 10, observed in great numbers in a malignant adenoma of the intestine. The lymph-spaces of this tumour are in places filled with spherical, dumb-bell, and chain-like forms, and it is only occasionally that a spiral character is assumed. Many of the bodies that on first view appear to be spirals are, however, capable of being interpreted as composed of a number of closely approximated dumb-bell forms which have assumed a regular zigzag arrangement.

The observations now recorded may be held to support certain of the conclusions already advanced by Mr. Henry Wade and one of us—namely, those regarding the frequent presence in carcinomatous tumours of special intranuclear bodies which persist during the division of the cells, the occurrence of intra-cellular and extra-cellular amœboid bodies and the contention that the great activity of the polymorphonuclear leucocytes is a manifestation of a phagocytic action directed against a specific parasite. Whether the speculations regarding the exact nature of the parasite and its life cycle were near the mark or not is a comparatively trivial matter.

In conclusion, we would acknowledge our indebtedness to the persons already named who have kindly supplied us with tissues, and also to Dr. M. B. Hannay who has sent us many tumours that have been of much value to us in our work.

Cairo, School of Medicine (Egyptian Government, Ministry of Education).—Assistant to the Professor of Pathology. Salary £E. 320 per annum.

Colchester, Essex and Colchester General Hospital.—*House* Physician. Salary £80 per annum, with board, residence, and washing.

Coventry and Warwickshire Hospital.—Junior House Surgeon for six months. Salary £60 per annum, with rooms, board, washing, and attendance.

Devon County Asylum.—Assistant Medical Officer. Salary £140, with board, apartments, and laundry.

Devonport, Royal Albert Hospital.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, &c.

"Dreadnought" Hospital, Greenwich.—Pathologist. Salary £100 per annum.

Egyptian Government, Kasr-El-Ainy Hospital.—Resident Medical Officer. Pay £250 a year, with quarters, servants, washing, coals, and light.

Egypt, Public Health Department.—Sub-Inspector of Ophthalmic Hospitals.

Gloucester, General Infirmary and the Gloucestershire Eye Institution.—Assistant House Surgeon for six months. Salary at rate of £30 per annum, with board, residence, and washing.

Grimsby and District Hospital.—Resident House Surgeon. Salary £100 per annum, with board, lodging, and washing.

Huddersfield Infirmary.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

Hull, Royal Infirmary.—Casualty House Surgeon. Salary £50, with board and lodging.

Ipswich, East Suffolk and Ipswich Hospital.—Third House Surgeon. Salary £50 per annum, with board, attendance, and washing.

Lancaster, Royal Lancaster Infirmary.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, attendance, and washing.

Liverpool Dispensaries.—Assistant Surgeon, unmarried. Salary £100 per annum, with board and apartments.

Liverpool, Royal Southern Hospital.—Resident Pathologist and Registrar. Salary £100, with board and residence.

Manchester, Ancoats Hospital.—Resident House Physician.

Manchester, Monsall Fever Hospital.—Fourth Medical Assistant. Salary £100 per annum, with board, lodgings, and washing.

Mickleover, Derby County Asylum.—Junior Assistant Medical Officer. Salary £120, rising to £150 per annum, with apartments, board, washing, and attendance.

Norfolk and Norwich Hospital.—House Surgeon. Salary £80 per annum, with board, lodging, and washing. Also Two Assistant House Surgeons for six months. Salary £20, with board, lodging, and washing.

North-Eastern Hospital for Children, Hackney-road, Bethnal Green, E.—House Physician for six months. Salary at rate of £60 per annum, with board, residence, and laundry.

Northampton, Borough of.—Medical Officer of Health. Salary £400 per annum, rising to £500, with reasonable carriage expenses.

Northampton General Hospital.—Assistant House Surgeon, unmarried. Salary £50 a year, with apartments, board, washing, and attendance.

Paisley, Infectious Diseases Hospital.—Assistant Medical Officer. Salary £100 per annum, with board, washing, and attendance.

Plymouth, South Devon and East Cornwall Hospital.—*House Physician* for six months, renewable. Salary £50, with board, residence, and washing.

Rotherham Hospital and Dispensary.—Assistant House Surgeon. Salary £80 per annum, with rooms, commons, and washing.

Royal Dental Hospital, *Leicester-square.*—Morning House Anæsthetist. Salary £50 per annum.

Royal Eye Hospital, St. George's-circus, S.E.—Refraction Assistant. Salary £40 per annum. Also Clinical Assistants.

Royal Institute of Public Health.—*Demonstrator of Comparative* Pathology and Bacteriology.

Salford Royal Hospital.—Junior House Surgeon. Salary at rate of £50 per annum, with board and residence.

Southampton, Royal South Hants and Southampton Hospital.—House Physician. Salary £100 per annum, with rooms, board, and washing.

Southport Infirmary.—Residents' Senior House Surgeon. Also Junior House and Visiting Surgeon, unmarried, for six months. Salary of Senior at *rate of £80* per annum, and *of Junior £70* per annum, with residence, board, and washing.

Stockport Infirmary.—House Surgeon. Salary £100 per annum, with board, washing, and residence. Also Junior Assistant House and Visiting Surgeon. Salary £50 per annum, *with board*, washing, and residence.

Teignmouth Hospital, South Devon.—House *Surgeon. Salary £70* a year, with board, lodging, and washing.

Whitehaven and West Cumberland Infirmary.—Resident House Surgeon. Salary £120 a year, with board and lodging.

Zanzibar Government.—Bacteriologist. Salary £300 a year, rising to £400, with free quarters, &c.

Births, Marriages, and Deaths.

BIRTH.

Eccles.—On the 29th July, at 124, Harley-street, W., the wife of W. McAdam Eccles, M.S., F.R.C.S., of a son.

MARRIAGE.

Archibald—Riddle.—On July 25th, at Holy Trinity, Upper Tooting, Richard James Archibald, M.R.C.S., L.R.C.P., to Gertrude Florence, eldest daughter of Frederick Henry Brimble Riddle of Upper Tooting.

DEATH.

Brumwell.—On July 29th, at Newcastle-on-Tyne, aged 54 years, Ernest Brumwell, M.D., M.R.C.S., L.S.A., *of North Shields.*

Notes, Short Comments, and Answers to Correspondents.

GARBAGE MONGERS FINED.

At *the Old-street police station* Mr. Cluer *recently* fined a man named Shuttleworth £50, with £26 5*s.* costs, upon three summonses charging him with having on his premises 250 cases of condensed milk on March 1st, 95 such cases on June 8th, and two pieces of beef, all intended for human food and unfit for such a purpose. The cases each contained four dozen tins and some of the marks showed that they had been returned from South Africa. The owner was described as an *owner of house property, carrying on registered common* lodging-houses and an eating-house, and it was part of the case *for* the prosecution that the blown tins of condensed milk were *to* be sold to the inmates of the common lodging-houses. The defence consisted *of* a story that the shed in which the stuff was found was sublet by the defendant to two men who had *deposited it there until* it could be sold as food for pigs. This was not corroborated. The fine inflicted was promptly paid. In another case, *on* July 25th Julius Winterman, a baker and confectioner of 144, High-street, Kingsland, was fined £10, with £5 5*s.* costs, or in default sentenced *to two* months' *imprisonment*, *for being in possession* of 455 tins of condensed milk which was unfit for human consumption. Mr. Young, who defended, put in an invoice showing that the prisoner had bought 380 tins at 1*d.* a piece. Mr. Young added that it was a fair price for a quantity and that the prisoner had dealt with the same firm for three years without complaint. Mr. Cluer, the magistrate, is reported as saying: "Some people do not seem to care how much they poison London. Those who sold these tins to the defendant ought to be proceeded against, for they ought to know that the stuff was bad if they could make a profit and sell at 1*d.* per tin." We quite agree with Mr. Cluer, but the penalty for an offence of this kind should be made much heavier than it is. There is little use in holding conferences about physical degeneration, infantile mortality, and other similar matters if unscrupulous dealers are allowed to sell to the poor what is neither more nor less than poison.

TRUE CLEANLINESS.

To the Editors of THE LANCET.

SIRS,—Does your correspondent Mr. W. W. Strickland (THE LANCET, July 27th, p. 270) mean that a man, whether a Chinaman or a North Italian, or any one else, employs a more cleanly and more sanitary method of blowing his nose when he uses his fingers only for the purpose than he would if he used a pocket-handkerchief? If not, what is the practice of the native of India to which he refers? If so, are we recommended, exhorted, and ordered not to spit in streets, railway-carriages, and other public places but at the same time urged to blow our noses in public and in private "with *our* fingers"? If this is the case I am afraid that without making any admission as to the length of my nose or the absence or presence of fur on my face I must remain unconvinced, insanitary, and uncleanly. Perhaps, however, I have misunderstood, being A LAYMAN.

July 31st.

COLOTOMY—CONSTIPATION.

WE have received several replies to the inquiry of "The Sufferer (a Medical Man)" which appeared in THE LANCET of July 20th, p. 204. From these we make the following extracts:—

1. A correspondent writes that personal experience enables him to recommend a trial of liquid paraffin as described by Dr. Neville Wood in the *West London Medical Journal* in April, 1906. He also mentions parolein and regulin, the latter of which is reported on in our "Analytical Records" in THE LANCET of June 29th, p. 1722.

2. "Octogenarian" suggests that for some time before the performance of the colotomy there had been obstruction which might have been met by a long-continued liquid dietary, and if so, the muscular contractility of the intestine would be enfeebled from diminished use. In such circumstances drastic purgatives would be injurious. He advises the patient to eat very slowly, masticating thoroughly, and not to drink whilst eating in order that an abundant flow of saliva should accompany the food into the stomach. A drink of hot water afterwards "would be to the good." All forms of alcoholic stimulant should be avoided. If milk is largely used it should be in the form of junket either by itself or with various kinds of fruit. Fatty and oily matter—fat bacon, butter, suet, cream, and such like—should be taken freely. Treacle and coarse oatmeal in the form of the old-fashioned "parkin," stewed figs, and French plums may be taken. If the patient is capable of brisk exercise nothing can be better than a five or six mile walk within the hour. For patients who can take it a "cold tub" when getting out of bed in the early morning is of great value. For medicine he recommends the rather startling combination of small doses of hyoscyamus and nux vomica—one grain of each extract in a pill three times a day. (We consider this dose of nux vomica positively dangerous.) If the patient is *greatly* tempted to use an aperient it had better be one drachm of either castor oil or olive oil every

become muddy and yellowish-green, followed by a yellow precipitate settling out, or they may assume a muddy green or a muddy bluish-green state. In a stage further on, with the change of colour, there may be a translucent instead of a muddy state. The microscope shows that associated with these conditions there is a progressive diminution of the size of the precipitated particles, and the diminution may advance till they are no longer susceptible of being perceived. When the translucent stage is reached the particles may be of sufficient fineness to remain suspended in like manner to what occurs in the case of an emulsion.

The variation in the colour of the contents of the test-tube is easily to be accounted for. The precipitate is yellow and the liquid out of which it is deposited is blue. According to the relative proportions of these two colours present, so will be the colour of the admixture.

Thus far what has been dealt with resolves itself simply into an alteration of the physical character of the precipitate. By virtue of an inhibiting agency upon coalescence the newly formed suboxide shows itself in a form varying according to the relative coalescing and inhibiting powers existing, these standing in proportion to the specific amounts of reducing and inhibiting materials present.

I have already entered fully into the consideration of creatinine as an inhibitor of suboxide coalescence and have shown that it possesses great power in this direction. I should say that it is the great modifier of the physical character of the precipitate as it is found to be modified by the influence of the urinary constituents. Seeing, as has been learnt from the experimental evidence adduced, that one milligramme of creatinine is capable of modifying the character of 200 milligrammes of suboxide precipitate, it is conceivable that so far as this action is concerned the amount of creatinine present in the urine may suffice to account for the production of the altered state in which the precipitate falls in the circumstances that are being referred to.

It is noticeable in connexion with urine testing that when the precipitate is formed it afterwards, during the process of boiling, more or less speedily changes colour in the direction from yellow to red. With this change the precipitated particles are observed to group themselves into clustered masses representative of a coarser state. Boiling briskly promotes this process of agglomeration.

The other points to be considered in connexion with the anomalous or modified reaction are delay of precipitation, and the occurrence of reduction without precipitation, in which case the blue colour of the test solution becomes replaced, when the reduction is complete, by a colourless state.

It is not infrequently noticeable on testing urine that delay, it may be for what appears a considerable period, of precipitation occurs without any apparent change of colour and then all of a sudden a well-marked precipitate becomes developed. It seems as if reduction was from some cause or other for a time delayed and the impression may be formed that no reaction is going to be produced. In connexion with this occurrence it may be remarked that the amount of sugar present has a marked influence on the result, even in the absence of extraneous matter to produce a complicating effect. For instance, experimenting with Fehling's solution and a pure solution of sugar reveals the fact that precipitation takes place much more rapidly when a large quantity of sugar is present than when only a small quantity exists. Immersing two tubes in the saline bath, one containing one cubic centimetre of a 1 per 1000 solution of dextrose and one cubic centimetre of adjusted Fehling's solution, and the other one cubic centimetre of a 5 per 1000 sugar solution and one cubic centimetre of ordinary Fehling's solution, it is observable that whilst precipitation in the latter almost instantly appears there is some amount of delay before signs of it are visible in the other. It must be borne in mind with reference to the mechanism of reduction that the sugar does not in a direct manner act upon the cupric oxide. It is through the breaking-down influence of the alkali contained in the test on the sugar that the effect is brought about. Without the alkali no reduction would occur.

When delay of precipitation occurs without loss of blue colour it may be taken to be the result of delayed reduction. The delay of precipitation attended with the loss of blue colour constitutes an event of a different nature. Reduction takes place but the reduced oxide instead of being precipitated is held in solution. I have spoken of creatinine in relation to suboxide precipitation and have discussed at some length on the great power it possesses of modifying the character of the precipitate. The retention of the suboxide in an unprecipitated state is another matter—one that is mixed up with complicated associations, as will be seen from the consideration that will now be given to it.

Creatinine, dealing with the quantity existing in healthy urine, has but a limited power in delaying suboxide precipitation, and the power is only made manifest when the amount of suboxide being dealt with is exceedingly small. In the case of one cubic centimetre of a 1 per 1000 solution of sugar, one cubic centimetre of adjusted Fehling's solution, and one milligramme of creatinine compared with the counterpart without the creatinine, marked delay is seen to occur. With a larger quantity of suboxide, however, brought into the question, as, for instance, when a 5 per 1000 solution of sugar is used with the ordinary Fehling's solution, it may be said that practically no material indication of delay is perceptible. In urines giving the anomalous reaction it may be considered that somewhere about 3, 4, or possibly 5, per 1000 of sugar may be reckoned to be present, from which it follows that the creatinine constituent cannot be regarded as answerable to any material extent for the delaying effect that may be noticed to occur.

Although potash promotes the destruction of creatinine, its addition has the effect of rendering delay in the occurrence of precipitation more pronounced. For perspicuously showing this let one cubic centimetre of a 2 per 1000 solution of sugar be taken with one cubic centimetre of adjusted Fehling's solution and one milligramme of creatinine in one tube, and in the other a similar mixture with the addition of one drop of a 40 per cent. solution of potash. Precipitation in the tube containing the potash is seen to occur considerably later than in the other. With five drops of potash solution instead of one drop the interval is greatly extended. With creatinine as the inhibitor of precipitation it is inconsistent that the promotion of its destruction should lead to a manifestation of increased efficiency.

I have shown that urea, from which ammonia is liberated by the alkali of Fehling's solution, has the effect of increasing the delaying action seen in working with a 1 per 1000 solution of sugar to be exerted by creatinine. Taking the experiment with one cubic centimetre of a 1 per 1000 sugar solution, one cubic centimetre of adjusted Fehling's solution and one milligramme of creatinine and a counterpart with the addition of one drop of a 40 per cent. solution of urea, a considerable interval is found to occur between the periods of the two precipitations, showing the delaying action exerted by urea.

The delaying action exerted by urea is increased by the addition of potash, which has the effect of promoting the liberation of ammonia. This can be well shown by operating upon urine that gives a traceable indication of sugar reaction with Fehling's solution. It has been stated that urea alone and potash alone produce an inhibiting effect. With the two combined the effect is increased. For illustration, let one cubic centimetre of the urine and one cubic centimetre of ordinary Fehling's solution be taken as representing the control to be immersed in the saline bath by the side of a second tube containing a counterpart with two drops of a 40 per cent. solution of urea, a third with two drops of a 40 per cent. solution of potash, and a fourth with two drops each of the urea and potash solutions mixed. In the first, precipitation quickly occurs and is followed shortly afterwards by its appearance in the second, whilst an interval of several seconds may lapse before it subsequently appears in the third, and again another similar or even longer interval before it appears in the fourth.

With respect to ammonia, in a direct manner derivable from the urine, as an inhibiting agent, the following piece of evidence, derivable from the extensive series of experiments recorded in the communication of Dr. A. M. Kellas and Dr. F. J. Wethered, referred to at the beginning of this article, appositely fits in. As a result of the experiments conducted with sodium urate on the one hand and ammonium quadriurate on the other, boiled with Fehling's solution, it is noticeable[1] that a certain amount of inhibiting effect occurred in the case of the latter. The only difference existing between the two cases is that in the one a sodium salt is present and in the other a salt from which ammonia would be set free in the process of boiling. The fact alluded to serves to add another link to the chain of evidence connecting ammonia with the inhibition phenomenon.

---

Ormond-street (9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2 30 P M.).

THURSDAY (8th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond street (2.30 P.M.), Tottenham (Gynæcological, 2.30 P.M.).

FRIDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (10th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St Mary's (10 P.M.), Throat, Golden-square (9 30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, &C.

MONDAY (5th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations.

TUESDAY (6th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

WEDNESDAY (7th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M: Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr Saunders: Diseases of Children. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. K. Scott: Diseases of the Eye. 2.30 P.M.: Operations. Dr. Robinson: Diseases of Women.

THURSDAY (8th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations.

FRIDAY (9th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. X Rays. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

SATURDAY (10th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. K. Scott: Diseases of the Eye. 2.30 P.M.: Operations. Dr. Robinson: Diseases of Women.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1907, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in THE LANCET of July 6th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1907 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

quantity of grape sugar—or a body giving identical reactions —is probably an almost constant constituent of normal urine." At pages 1140–1141 they enter with considerable detail upon the subject and furnish a supply of figures from different sources. As the question of quantity has underlying physiological and other points of importance connected with it, it ought not, I consider, to be allowed to pass without attention being given to it. "We have already stated," they say, "that we venture to differ from Dr. Pavy's method of stating his results. We find by the safranine test that from 0·2 to 1·5 per 1000 [transformed by me from per cent. to per mille expressions] of a body or bodies reacting identically with grape sugar may normally be present, say 0·8 per 1000 (approximately) as an average by the experiments so far carried out. Diet and amount of exercise, as well as specific gravity of the urine, may alter the values considerably. In very concentrated urine values up to 2·5 per 1000 might be found. Above 3 per 1000 should probably be regarded as abnormal, *provided the diet has been normal*, and above 4 per 1000 should, in our opinion, be regarded as of pathological import. Pavy gives 2·79 per 1000 as an average of several experiments (his values varying from 0·91 to 4·88). This value is certainly too high if seriously referred to sugar alone, and has been obtained because the reducing action of creatinine, creatine, mucin, and urates has not been allowed for. Dr. Pavy is aware that these substances exercise reducing action but does not regard them as 'answering for much in this direction.' In our opinion these substances may represent 50 per cent. or more of the reducing effect observed."

Looked at in its entirety what is here stated is a little mixed up and I cannot consent to safranine being placed in a position to settle the question that confronts us. I hold that a very incorrect notion exists with regard to the condition of normal urine in relation to sugar and in substantiation I will proceed to examine the points bearing on the matter.

In my recent work on "Carbohydrate Metabolism and Diabetes" I have given the results derived from 42 observations conducted upon the urine of the rabbit, cat, dog, horse, and the human subject. The point raised regarding the deduction to be made from my values for the reducing action of other urinary ingredients existing in addition to sugar does not bear anything approximating to the significance that is shown in the above remarks to be claimed for it. The matter is open to being put into shape for being viewed through definite terms of expression and let us see what the reduction to be made in reality amounts to.

Both creatinine and creatine are named amongst the reducing substances but it is generally considered that the former only is in ordinary circumstances present. Mucin, although enumerated, does not possess, *per se*, reducing power. Only creatinine and uric acid in the list are consequently left, and through what has been said in a former part of this communication about these bodies, to which I may refer the reader, a definite estimate of the effect producible by them can be framed.

For average conditions it was found to work out that, expressing the reducing power exerted by them in terms of glucose, the figures representative of the effect produced by the amounts respectively present in the urine stand at 0·25 per 1000 for creatinine and 0·35 per 1000 for uric acid, making 0·60 per 1000 for the two. The average total reducing power of urine, derived from my observations and mentioned in the quotation given, amounts to 2·79 per 1000. From this the deduction to be made for creatinine and uric acid is 0·60 per 1000, which brings the figures for glucose to 2·19 per 1000. In taking exception to my assertion that I did not consider the reducing substances apart from sugar could be regarded as answering for much in the sum of reduction occurring Dr. Kellas and Dr. Wethered hazard the opinion that they may represent 50 per cent. or more of the reducing effect observed. Upon the basis of the calculation given the figures expressive of total reducing effect—viz., 2·79—become reduced by deducting from them those for the other than sugar reducing action to 2·19, giving for this other than sugar reducing action the proportion of a little over one-fifth of the whole in place of the suggested 50 per cent. or more.

Dr. Kellas and Dr. Wethered afterwards set forth results obtained by various other observers and in the main they are seen, as is admitted, fairly to agree with mine. Amongst the results mentioned I noticed those of Balsch, referred to below, which I submit ought not to have found a place where they stand. After stating that "according to Balsch the quantity of glucose averages 0·005 per cent. and of total carbohydrates about 0·01 per cent.," there follows the remark that the results "are probably considerably under the true quantities present," succeeded by reference to an author who says that the test made use of cannot be regarded as in any way quantitative in its indications. The impression created by the figures here given may have the effect on the mind of reducing to insignificance the amount of sugar present in normal urine, but the cause of truth is not likely to be benefited thereby.

Not only must it be considered as thoroughly established that sugar in decidedly manifest quantity exists in normal urine, but recent advance of knowledge has placed us in a position to bring sugar differentiation into connexion with the matter. Dextrose was formerly thought to be the kind of sugar present within the system. It is now susceptible of being shown, however, that such is not exclusively the case. A joint paper by Pavy and Siau is to be found in the *Journal of Physiology*, Vol. XXVI., 1901, bearing the title, "On the Nature of the Sugar Present in Normal Blood, Urine, and Muscle," in which demonstrative evidence is supplied in proof of the presence of sugar of lower cupric oxide reducing power than dextrose. A maltose type of sugar is recognisable through the character of the osazone crystals obtainable, and it may be inferred that dextrinoid bodies are also present.

In the case of urine it is particularly noticeable that low cupric oxide reducing material is found to exist. About 60, indeed, is found to represent the average associated cupric oxide reducing power, viewed in relation to 100 reckoned as the cupric oxide reducing power of glucose. Thereby, on account of the lower cupric oxide reducing power possessed by the material in comparison with glucose, in terms of which the expression is made, what is indicated as amounting to 60 parts stands in reality as the equivalent of 100 parts. Owing to this position of matters the indication afforded by a quantitative examination that has not been preceded by hydrolysis is only representative of a little more than half of the carbohydrate actually present.

In the series of observations upon the urine of various animals, to which allusion has been made, titration was in every case effected before and after hydrolysis, and when 2·79 per 1000 was spoken of as representing the average amount of sugar for the specimens from the human subject it referred to carbohydrate matter estimated before hydrolysis which was shown by estimation after hydrolysis to amount to 4·63 per 1000. With respect to these increased figures resulting from hydrolytic action, there can be no suspicion of their being derived from cupric-oxide reducing bodies other than of a carbohydrate or of a glucoside nature, inasmuch as the process adopted for effecting hydrolysis has no action in the direction of raising the cupric-oxide reducing power of the other bodies.

I consider that valuable information from divers points of view is derived from the subjection to hydrolysis that was adopted in the observations to which I have been referring. Taking the urine before and after hydrolysis gives a twofold result which adds materially to the weight of the evidence supplied. Throughout the 42 observations recorded a striking consistency is noticeable in the results obtained before and after hydrolysis, and looked at altogether no doubt can be left in the mind that in the first place a very measurable quantity of sugar is present in normal urine and in the next that much fluctuation in the quantity exists in different instances. The highest figures of all were derived from the urine of a rabbit where 8·80 per 1000 constituted the amount indicated before hydrolysis and 16·54 after. The lowest figures were likewise derived from the rabbit and stood at 0·68 per 1000 before hydrolysis and 1·80 after. The mean figures for the 16 observations upon the rabbit were 3·69 per 1000 before hydrolysis and 7·03 after.

It is found that the degree of concentration of the urine constitutes a main factor in determining the extent of sugar indication presented. As an illustration in connexion with this point I may refer to two specimens of normal urine passed by a person within a few hours of each other. One had a specific gravity of 1008 and gave a sugar indication of 0·91 per 1000 before hydrolysis and 1·89 after. The other had a specific gravity of 1024, which was associated with a sugar indication of 2·87 per 1000 before hydrolysis and 5·05 after. Common experience it may be further said shows that it is especially with high specific gravity urines

Three Clinical Lectures
ON
GENERAL SURGICAL ANÆSTHESIA.

Delivered at the London Hospital,

By FREDERIC W. HEWITT, M.V.O., M.A.,
M.D. Cantab.,
EMERITUS LECTURER ON ANÆSTHETICS.

LECTURE III.[1]

Delivered on June 28th, 1907.

Certain Interesting Side Issues in Anæsthetisation.

Gentlemen,—I propose to conclude this short course of lectures by referring to certain interesting points connected with general anæsthesia.

A Note on the Inhalation of Nitrogen.

Several years ago, at the instigation of the late Sir George Johnson, I administered practically pure nitrogen and nitrogen with small proportions of oxygen up to 7 per cent. to several patients at the Royal Dental Hospital. Sir George Johnson believed that pure nitrous oxide produced its anæsthetic effects simply and solely by oxygen-exclusion and in order to prove this thesis he asked Mr. Woodhouse Braine and myself to conduct a number of administrations in order that he might compare the effects of the two gases. The results we obtained are elsewhere described in detail. I need only here say that the clinical phenomena produced by pure nitrogen were remarkably similar to those produced by pure nitrous oxide. Since conducting these administrations I have often regretted that I did not myself inhale some of the practically pure nitrogen which with some difficulty Sir George Johnson had obtained. You are doubtless aware that Snow, the great pioneer in the physiology of general anæsthesia, believed that all volatile narcotics acted in the same way, producing their effects (to quote his biographer the late Sir B. W. Richardson) by "arresting or limiting those combinations between the oxygen of the arterial blood and the tissues of the body, which are essential to sensation, volition, and all the animal functions." Like more recent observers, Snow had probably been struck by the remarkable similarity in the subjective sensations produced by the inhalation of different anæsthetics. The sensations which one experiences, for example, when inhaling nitrous oxide are remarkably similar to, and under certain conditions identical with, those felt when inhaling the diluted vapour of chloroform, ether, or ethyl chloride. Now it seemed to me that if the initial sensations under pure nitrogen could be shown to be of the same type as those which characterise the inhalation of the recognised anæsthetics considerable support would be given to Snow's theory. In other words, if, during the stage which immediately precedes loss of consciousness pure nitrogen produces that peculiar rhythmic "thrilling" or sensory disturbance which is experienced with all the usual anæsthetics, are we not justified in inferring that the action of these anæsthetics, whatever that action may be, is of the same nature as that of nitrogen? If so, nitrous oxide, ether, chloroform, &c., must act, as Snow believed, by limiting or arresting normal oxidation processes, for we cannot ascribe to nitrogen, which is undoubtedly an anæsthetic, any definite or specific actions.

Quite recently, through the kindness of my friend, Dr. B. J. Collingwood, demonstrator of physiology at St. Mary's Hospital, I have been furnished with some nitrogen containing only 0·75 per cent. of oxygen—i.e., practically pure—and I have been able to satisfy myself by inhaling this gas that the initial sensations are of the same type or character as those met with when inhaling nitrous oxide or weak atmospheres of ether, chloroform, or ethyl chloride. I may add that my friend, Mr. H. Bellamy Gardner, also inhaled some of this practically pure nitrogen and entirely agrees with me upon this point. It is obvious that we have only oxygen deprivation to reckon with when we inhale nitrogen by means of an apparatus with accurately working valves, so that all expirations escape. This form of inhalation simply means a rapidly progressive diminution in the normal oxygen supply—a state of anoxæmia.

As regards carbonic acid it is practically certain that the diminished oxygen intake leads to diminished carbonic acid production, and that this last-named gas is in no sense locked up in the circulation, for, although diminished in quantity, it can still escape from the blood with other expired gases. But however this may be, the interesting fact remains that the peculiar, pleasurable, and indescribable "thrilling" or vibration which is experienced under most anæsthetics is also met with under nitrogen, thereby strongly supporting Snow's contention that anæsthetics act by interfering with normal oxygenation in nervous and other tissues.

The Advantages and Disadvantages of the Trendelenburg Posture.

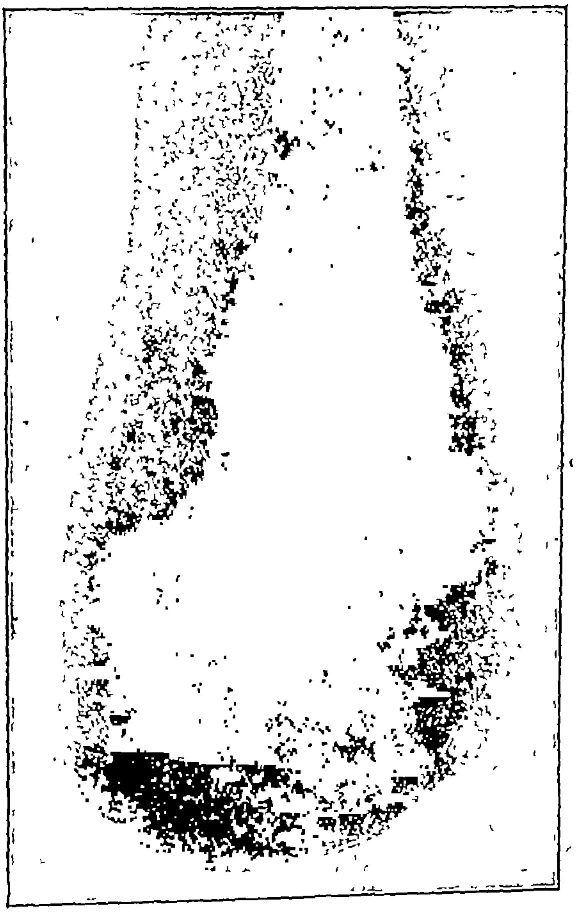
I referred in the last lecture to the remarkable fact that when the patient is lying in the feet-up position, or when he is placed in the Trendelenburg posture, intra-abdominal operations may be conducted during deep chloroform anæsthesia with little or no risk of acute circulatory shock. Although I have anæsthetised a large number of patients in the Trendelenburg posture for operations such as hysterectomy which, in horizontally placed patients under chloroform is often attended by marked circulatory shock, I have never witnessed, with this posture, anything more than comparatively temporary disturbances of cardiac action. As a general rule, indeed, patients thus placed preserve a good pulse, colour, and respiration, even though they may be deeply under chloroform, the feet-up posture preventing that accumulation of blood within the splanchnic area which always takes place, to a certain extent, during deep chloroform anæsthesia in the horizontal posture. The heart and lungs being better supplied with blood are able to preserve a fuller arterial system—i.e., a higher blood pressure—than when the patient is horizontal. This higher blood pressure not only counteracts any cardio-inhibitory effects which may arise from surgical causes, but by keeping the respiratory centres well supplied with blood it maintains a high standard of respiratory action. The better arterial pressure produced by the feet-up posture has been demonstrated experimentally by Leonard Hill, and it is this increased pressure which distinguishes the deeply chloroformed patient in this posture from the similarly deeply chloroformed patient in the horizontal posture. We can thus understand how the feet-up posture helps to prevent circulatory shock, chiefly if not wholly of vaso-motor origin, for it is obvious that a surgical injury capable of producing a certain fall of blood pressure from an effect upon the vaso-motor centres would produce a much more marked effect if the patient's blood pressure were at the time low, as it would be in the horizontal posture, than if it were higher, in the feet-up posture. It would seem, then, that the Trendelenburg posture tends to prevent circulatory shock, whether cardio-inhibitory or vaso-motor in type. Sometimes, as I have mentioned to you, one may notice certain cardio-inhibitory phenomena in patients placed in this posture, but they do not, as a rule, assume serious proportions. There are, of course, many operations likely to produce circulatory shock which cannot be performed in the Trendelenburg posture, but I cannot help thinking that when chloroform is to be employed surgeons would do well to adopt this posture whenever practicable. There is little or no point in the procedure when ether is the selected anæsthetic, because with this agent arterial pressure is little if at all affected. Nor is there much point in the Trendelenburg posture when only moderate chloroform anæsthesia is required. It is principally indicated when the deepest form of chloroform anæsthesia is needed and the patient is to undergo an operation liable to be attended by circulatory shock.

It is generally believed that difficulties occurring in the feet-up posture are referable to the abdominal contents pressing unduly upon the diaphragm but I believe this to be an erroneous view. That respiratory difficulties are not uncommon in patients thus placed may be freely admitted, but these difficulties, which are always most pronounced in plethoric, thick-necked, or obese subjects, are, I submit, dependent upon venous engorgement of the tongue and adjacent parts. I have often known stertor to be at once evoked by placing the patient in the Trendelenburg posture without altering the relations between the head and trunk; and I have often had to maintain tongue traction and to adopt other measures for keeping the upper air passages satisfactorily open. It is important that the head should not be secured. About a quarter of an inch of the anterior extremity of the os calcis is then removed and the os calcis is brought into apposition with the tibia and fixed there with a six-inch excision pin driven through the sole with about two inches left projecting. A second pin may be used and passed through the tibia into the os calcis from the front and tension subsequently—i.e., after suture and dressing—kept up on the projecting ends by rubber tubing passed in figure-of-eight round them. After suture of the flaps the stump is put up preferably in plaster for a fortnight, when the stitches and pins may be removed. Plaster is then re-applied and the patient is allowed to get about with the leg flexed on a peg leg. Plaster should be continued until firm bony union has occurred and the patient should not be allowed to put the foot to the ground under three months but should continue to use the peg leg. At the end of three months an artificial foot can be fitted and gradually made use of.

---

[1] Lectures I. and II. were published in The Lancet of July 20th (p. 139) and 27th (p. 212), 1907, respectively.

FIG. 1.



The stump in Case 1 three months after operation.

FIG. 2.

The stump in Case 1 a year after operation. The ridges on the skin are due, of course, to impressions left by a coarse stocking.

CASE 1. *Infantile hemiplegia involving left arm and leg.*—The patient, a man, aged 30 years, was admitted to the Metropolitan Hospital on March 31st, 1906, with the following history. When one year old he had had infantile hemiplegia which left partial paralysis of the left hand and leg below the knee. He had had no treatment in the past. The deformity of the foot had gradually increased. He had worn a high boot for the previous six months (O'Connor extension) but it had constantly given away and had not afforded him much support. He was unable to work as a labourer owing to difficulty in standing. The left arm and leg were much wasted. The foot was in the position of marked equino-varus with the dorsum directed downwards. Electrical reactions.—The left thigh was normal. The superficial calf muscles reacted to strong galvanic and faradic currents. The tibialis posticus and flexor longus digitorum reacted to very strong faradism and slightly to very strong galvanism. There was no reaction in the extensors. The peronei reacted to strong faradism and galvanism. The movements at the hip and knee were good. The left leg measured to the malleoli was one inch shorter than the right.

The operation performed on April 17th, 1906, was practically identical with the one described above except that the internal malleolus was removed and only the cartilaginous surface of the sustentaculum tali cut off. Two steel pins were used and cross tension was kept up on the projecting ends by means of rubber drainage tubing. The stump was put up on a splint for ten days and then the pins and stitches were removed. Plaster was then applied and the patient was allowed up on a peg leg. There was firm bony union at the end of four weeks. An artificial foot was fitted, and the patient began to walk on it on Sept. 8th—i.e., five months after the operation. Up to the time of the foot being fitted the patient walked about well on the peg leg. He can now walk well on the artificial foot without additional support. The stump is quite firm and has no tender spot.

CASE 2. *Infantile hemiplegia involving the right arm and leg and slightly also the left leg.*—The patient, a man, aged 44 years, was admitted to the Metropolitan Hospital on June 28th, 1906. The deformity in this case was almost identical with the first but the varus was rather less marked. An additional factor in this case was some paresis of the extensors of the opposite leg with rectangular talipes. The operation was identical except that rather more of the front of the os calcis was removed as the plantar flap had been cut a little too short. When the dressings were removed the central portion of the anterior flap was found to be gangrenous and was cut away. Some blood clot had collected underneath the flap. The tourniquet in this case was not removed until after the wound had been closed and firm pressure applied with dressing and bandage. As there is a certain amount of slack under the anterior flap this is probably an unwise proceeding in these cases. Subsequent skin-grafting produced a good scar but a little depressed in the operation, which was quite a short one, to be completed. Respiration had now been suspended for (?) 20 to 25 seconds and the patient was beginning to show signs of asphyxia. I passed my finger to the back of the throat and to the laryngeal orifice without causing any respiratory response. Pressure upon the chest walls effected only an imperfect expulsion of air and little or no entry of air took place from elastic recoil. With the help of the operator, whose assistance was of the greatest possible value, the patient was rapidly placed upon the floor in the lateral posture. Chest compression was now followed by slight improvement. The improvement, however, was of short duration and it was obvious from the open eyes, the dilated pupils, and the cyanosis of the patient that a state of acute asphyxia was present. Accordingly I sponged out the fauces and commenced artificial respiration by Silvester's method. At first there was little, if any, air entry, and I thought it would be necessary to perform laryngotomy. Fortunately, however, in about one and a half or two minutes from the commencement of the asphyxial symptoms air began to enter the lungs freely and recovery quickly ensued. The patient was replaced in the chair. There was no after-depression of any kind. Recovery of consciousness took place in much the same way that it would have taken place had no intercurrent asphyxia arisen.

There can be no doubt, I think, that this was a case of intercurrent asphyxia due to the entry into the larynx during anæsthesia of a quantity of viscid mucus and saliva which, owing to the local conditions present, could not be swallowed. The act of deglutition—one of nature's two safeguards against laryngeal invasion—is not, as a rule, annulled by nitrous oxide, but if, as in the above case, this act be physically impossible, it would seem that a collection of fluid within the oral cavity may, in the sitting posture, enter the larynx and set up spasm. The same is probably true of the semi-recumbent and horizontal postures. It is curious that no cough was excited by the passage of the fluid into the larynx. As a general rule, coughing, nature's other safeguard against laryngeal invasion, is not annulled by nitrous oxide and is excited, even at the height of anæsthesia, by the entry of fluid into the larynx. It is probable, however, that in this patient, as in certain others that one anæsthetises for throat operations, the larynx was unusually insensitive. It is easy to be wise after the event and the lesson to be learnt from this interesting case is that in patients troubled with excessive mucous and salivary secretion, in whom deglutition is difficult, general anæsthesia should be induced in the lateral posture in order that the fluids in question may not enter the larynx. With the experience of the above case before me I am inclined to think, too, that it would have been better to have selected the C.E. mixture as the anæsthetic and to have administered it to a moderate degree of anæsthesia whilst the patient was lying as suggested. By this plan the buccal secretions would have collected in the dependent cheek and the anæsthesia would have been of such a character that it would have allowed of the insertion of a gag and of frequent sponging during the operation. Let me say, however, that the case I have described in no way invalidates the assertion that nitrous oxide when administered with a proper proportion of oxygen is the safest known anæsthetic. The asphyxial complication met with was neither due to the anæsthetic selected nor to the method of administration employed. It was, in fact, chiefly, if not wholly, caused by the posture in which the administration was conducted.

VACCINATION FEES.—The Cardiff board of guardians, at its meeting held on July 27th decided to reduce the fees for vaccination in Cardiff from 5*s* to 2*s*. 6*d*. and in the country districts from 6*s*. to 3*s*. 6*d*.—The Bodmin board of guardians at its meeting held on July 27th decided to reduce the vaccination fees. The minimum charge will be 3*s*. 6*d*., instead of 5*s*., in cases within one mile radius, and beyond that distance in some instances the fees are reduced from 8*s*. to 5*s*. 6*d*., and in others from 9*s*. to 6*s*. 6*d*.

LADY HEALTH VISITOR AT BATH.—In June last the corporation of Bath authorised the medical officer of health (Dr. W. H. Symons) to employ a lady health visitor for a few hours daily. Since the date of her appointment she has done good work in visiting the households of newly born children and in inquiring into the conditions of employment of married outworkers. When the question of continuing the services of this health visitor was being discussed at the last meeting of the corporation it is to be regretted that one member asked the council to pause before making the post a permanent one, for the lady appointed, he declared, was to go from house to house to harass the poor. This view was fortunately not held by the majority of the members of the council and the health visitor will still carry out her duties.

The Harben Lectures

ON

EXPERIMENTAL RESEARCHES ON SPECIFIC THERAPEUTICS.

Delivered at 20, Hanover-square, London, under the auspices of the Royal Institute of Public Health,

BY PROFESSOR PAUL EHRLICH, M.D.,

DIRECTOR OF THE KÖNIGLICHES INSTITUT FÜR EXPERIMENTELLE THERAPIE, FRANKFORT.

LECTURE III.[1]

Delivered on June 11th.

CHEMOTHERAPEUTIC STUDIES ON TRYPANOSOMES.

GENTLEMEN,—The substances which have hitherto proved efficient in combating trypanosomic infections can be divided into three groups—viz., (1) the group of the basic triphenyl-methane dyes, (2) the group of the benzidine dyes, and (3) the group of the arsenicals, with (4) salts of mercury, as adjuvantia.

Among the triphenyl-methane stains, which were first employed by Wendelstadt, parafuchsin is by far the most satisfactory. It is possible by prophylactic feeding with this drug to render mice for a long time resistant to trypanosomic infections, and I believe that this innocent substance might well be employed in the tropics for the prophylaxis of human sleeping sickness.

As regards the second type of remedies belonging to the benzidine group, trypan-red is a cotton dye which shows the remarkable feature of staining mice an intense red which remains fast for months. I have also prepared a number of similar dyes belonging to the benzidine series, some of which possess an even more powerful action than trypan-red. In several cases a blue dye belonging to the same group, which was prepared by Nicolle and Mesnil, has proved still more efficient.

The value of the arsenical substances which have for a long time been employed in the treatment of trypanosomic diseases was first recognised by Laveran. Later, it was discovered at the Liverpool School of Tropical Medicine that atoxyl was a far more powerful substance. It is prepared by treating aniline with arsenic acid. The makers believe it to be an anilide of arsenic acid—i.e., a compound in which the arsenic acid radicle is supposed to be attached to the amido group in a similar manner as the acetic acid is present in acetanilide. Now, as you all know, the ammonia radicle, which in aniline is very ready to react, has completely lost this property in acetanilide. This latter body is, in fact, almost an indifferent compound. Similarly, by the view that atoxyl was the anilide of arsenic acid, any further development of this compound was rendered impossible. I was, however, able to prove, together with Dr. Bertheim, that this compound is to be regarded as something entirely different—namely, that the amido group is quite free and that the arsenic acid radicle is attached to the benzol ring in the para position. Atoxyl must, therefore, be regarded as the sodium salt of paramido phenyl-arsenic acid. We have obtained a great number of substances derived from it and have tested them therapeutically.

Thus we found that by the introduction of the acetyl radicle into the amido group the acetyl-amido-phenyl-arsenic acid is produced which is far less toxic for mice than atoxyl. By means of this substance it is even possible to solve one of the most difficult therapeutic problems imaginable. For mice that have been infected with our most virulent strains and which, failing treatment, would die within three days, can in two-thirds of the cases be saved by this remedy if it is given 12 to 14 hours before death occurs in the control animals. Such curative results have never yet been published. For in previous communications there were mentioned almost exclusively experiments carried out at earlier periods of infection. In such cases acetyl-atoxyl cures mice in nearly 100 per cent. Unfortunately it is decomposed in other animals, especially in the horse, into acetic acid and aniline, and it cannot therefore be anything like so effective two agar tubes, one inoculated with blood obtained by pricking a cleaned finger and one inoculated with discharge from the wound in the neck, was sent to one of us. The agar tube inoculated from the blood from the finger was found to be contaminated and that inoculated from the discharge from the neck was found to contain staphylococcus pyogenes aureus. The staphylococcic opsonic index was found to be 1·1. Rigors continued daily to the 22nd, when the evening temperature was 103·6°. On the 23rd ten cubic centimetres of blood were withdrawn by venipuncture from the right basilic vein and two broth flasks were inoculated. An inoculation of 10,000,000 staphylococci was also given to the boy in case the infection should prove to be staphylococcal in origin. On the 25th some swelling was detected over the upper part of the right thigh and a free incision was made over the hip-joint and along the femur. Pus was found deep in the thigh in the track of the deep femoral vein at the apex of Scarpa's triangle and large drainage-tubes were inserted. On the same date one of the broth flasks was found to contain a pure culture of streptococcus pyogenes, while the second was found to be sterile. The boy's index against this streptococcus was taken and was found to be 0·66, and a vaccine was therefore prepared according to Sir A. E. Wright's method, and on the 28th the first dose, consisting of 10,000,000 dead streptococci, was given, the temperature then being 103·5° and the index to staphylococcus pyogenes aureus then being 1·2. The condition therefore appeared to be due to a pure streptococcus infection. On the 29th the index to the streptococcus had risen to 1·15 and on the 30th the evening temperature had fallen to 102·5°. On the 31st severe pain and some tenderness were felt in the upper part of the *left* thigh and half-drachm doses of citric acid were therefore given every four hours, with the result that in five days the left thigh was entirely free from pain or tenderness. On April 1st the index had fallen to 0·85 and the temperature had risen to 103°, and another 10,000,000 streptococci were therefore given, with the result that by the 3rd the index had risen to 1·2 and temperature had fallen to 102°. On the 4th the right leg was straightened out under an anæsthetic and a weight extension was applied to the leg. This evidently produced an auto-inoculation, as on the evening of the 4th the index had fallen to 0·9, to rise on the 5th without a dose of vaccine to 1·3, when the temperature was 101°. On the 7th and 11th the index fell below normal and 20,000,000 and 25,000,000 streptococci were inoculated respectively, with the result that the index rose to 1·8 and 1·6 on the 9th and 13th respectively. On the 14th there was a return of pain in the right leg and on the 15th the leg was again dressed and straightened under an anæsthetic, and there must again have been a considerable auto-inoculation, as on the 16th and 17th the index was 0·7. No vaccine was given on the 17th, as we hoped that the negative phase produced by the auto-inoculation would be followed by the positive phase, but as the index remained low on the 18th 12,500,000 were inoculated and the index rose to 1·45 on the 19th. On the 24th the boy was taken on the sea front in a spinal carriage and on the following day he complained of pain in the leg again and the temperature rose to 103°. Probably the moving to and from the spinal chair or the slight unavoidable jolting produced an auto-inoculation, as on the 26th the index had fallen to 0·95. 12,500,000 streptococci were inoculated on the 27th, but probably it would have been better not to have given it during this negative phase, as the index fell still further to 0·8 on the 28th, and did not rise to the normal line until the 30th, when the index to staphylococcus was also taken and found to be 1·1.

---

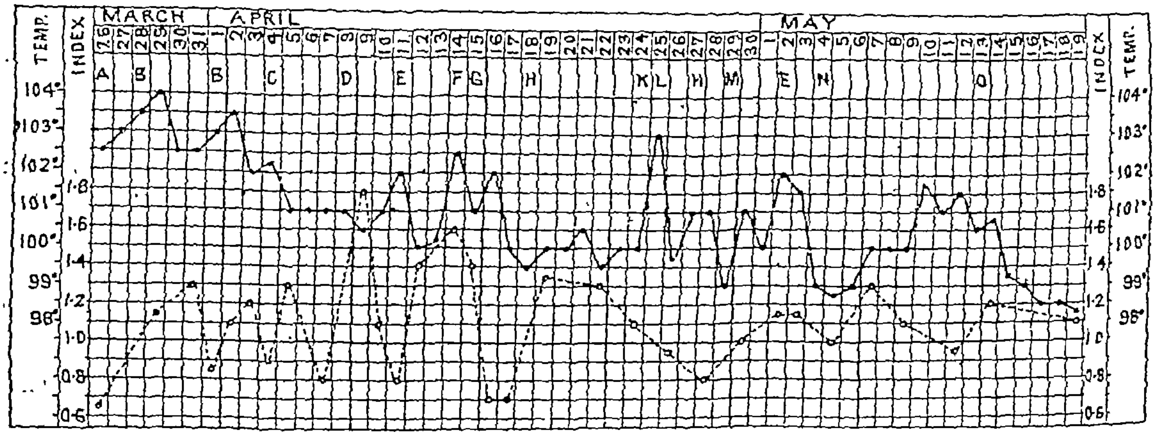
[1] Lectures I. and II. were published in THE LANCET of June 15th (p. 1634) and July 6th (p. 9), 1907, respectively.

As the marked improvement in the boy's general condition pointed to a local rather than a general condition as now being the cause of the elevated temperature, in order to obtain a freer drainage than was possible from the anterior incision, on April 29th a counter opening was made at the inner side of the thigh below the adductor muscles, and a tube was passed through. Notwithstanding the free drainage the temperature rose on May 2nd to 102°, and 25,000,000 streptococci were inoculated. On the 4th the temperature fell to 99°, where it remained for three days. For the following week the evening temperature was 100° to 101·8°. On the 12th the index had again fallen to just below normal and on the 13th 50,000,000 streptococci were inoculated with the result that the index rose and the temperature fell to 99·5°. On the 17th the anterior incision had entirely healed and as the discharge from the lateral counter opening had practically stopped the tube was removed. There was no further rise in the temperature and the case progressed steadily to complete recovery.

The chief feature of interest in the case is the non-development of the second threatened focus in the left thigh and this may, we think, be fairly ascribed to the vaccine and the administration of citric acid. There was, moreover, a marked general improvement after each inoculation with the vaccine, which, except in the case of the inoculations on April 27th and May 2nd, in every case was followed by a rise in the index within 24 hours, associated with a fall in the temperature. The boy was throughout kept out of doors from morning till night. The infection evidently took place at the time of the operation, the streptococci no doubt being already present in the discharging sinus and gaining admission through the wound in the vein into the general circulation and setting up rigors and a general septicæmia 15 days after.

We have considered it advisable to record this case, as it

CHART SHOWING PATIENT'S TEMPERATURE AND OPSONIC INDEX.



A Abscess in right leg opened. B, Inoculation with vaccine of 10,000,000 streptococci. C and G, Leg dressed under chloroform and straightened. D, Inoculation with vaccine of 20,000,000 streptococci. E, Inoculation with vaccine of 25,000,000 streptococci. F, Pain in right thigh. H, Inoculation with vaccine of 12,500,000 streptococci. K, Out in spinal carriage. L, Pain in leg. M, Counter-opening made under chloroform. N, Free discharge from counter-opening. O, Inoculation with vaccine of 50,000,000 streptococci. Pain was felt in the left hip from March 31st to April 4th. The upper (continuous) line shows the highest temperature recorded in the 24 hours and is plotted from the lateral columns marked "Temp." The lower (dotted) line shows the opsonic index to the patient's own streptococcus and is plotted from the lateral columns marked "Index." Owing to the blood having to be sent to one of us in London the dose of vaccine was given, as a rule, about 18 hours after the taking of the sample of blood on which the dose of vaccine was regulated.

from the Liverpool School of Tropical Medicine is most interesting as it demonstrates the successful result of the employment of supplementary doses of perchloride of mercury in the atoxyl treatment of animals infected with sleeping sickness.[2]

For man the combinatory treatment is of the greatest importance for a further reason. The complete sterilisation of the body—i.e., the total destruction of every parasite—is often only to be accomplished by the administration of doses which come very close to the lethal dose. Such a procedure directly endangering life may be permissible in the animal experiment, but never in man. One is, however, justified in hoping that it might be possible to cure the disease without endangering life by the simultaneous administration of three, four, or five substances, chosen in such a manner that their actions are concentrated on the parasites, whilst in the organism of the vertebrate host they are distributed over several different organs.

BODILY POSTURE AND CARDIAC PHYSICAL SIGNS.

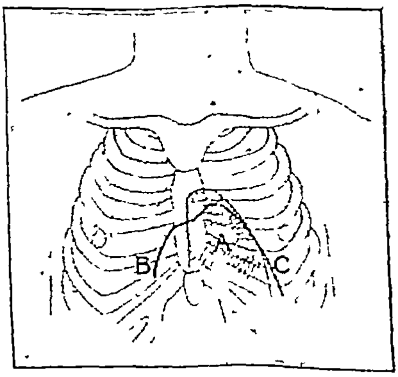
BY WILLIAM GORDON, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL AND TO THE WEST OF ENGLAND EYE INFIRMARY.

THE influence of bodily posture on cardiac physical signs is almost universally ignored. Only in the rarest instances is the record of a cardiac condition accompanied by a statement of the patient's posture at the time of observation. I propose to show that no description of the cardiac physical signs can be regarded as complete which does not include such a statement.

The Effect of Posture on the Normal Heart Dulness.

In this and in the succeeding divisions of my paper I shall only deal with the two commonest postures in which the chest is examined—the erect (sitting or standing) and the recumbent. When the recumbent position is exchanged for the erect the normal cardiac dulness generally falls and widens. The fall is not constant, being sometimes absent and sometimes replaced by a rise, but the widening is nearly invariable and is often considerable. Table I. gives the records of 36 unselected cases with normal hearts. In these it will be seen that the average fall of dulness when it occurred was rather greater than a rib's breadth and that the average widening was a little more than three-quarters of an inch. The change in the shape of the dulness is illustrated in Fig. 1.

FIG. 1.



Normal heart dulness The shaded area A = the dulness in the recumbent position The line B C = the outline of the dulness in the erect position.

The Effect of Posture on the Normal Heart Sounds at the Apex.

The same change of position also changes the character of the normal heart sounds, as they are heard over the apex of the heart. In the erect position the first sound is usually sharper, and the second sound duller, than in the recumbent position, so that the two sounds become much more like each other in the erect position than they are in the recumbent. The "lub dup" of the text-books is in most cases a fair description of the sounds of the apex only when the body is recumbent; "lup-lup" better describes them when the body is erect
